Mo.

e feel we should no longer delay in ex-
our complete satisfaction with your
otor which we have had installed in our
the past fifteen years. It has been
ical use every day at a total expense to
Of for brushes, and in all probability it
anc another fifteen years of service.

We thought you would be pleased to know
e satisfactior it has given us and the ex-
ly economical cost of its operation. It
give us pleasure to tell how well pleased
to anyone you may refer to us at any time.

truly yours,
AN AUTO CO. Inc.

Wagner Quality

That Means Satisfaction

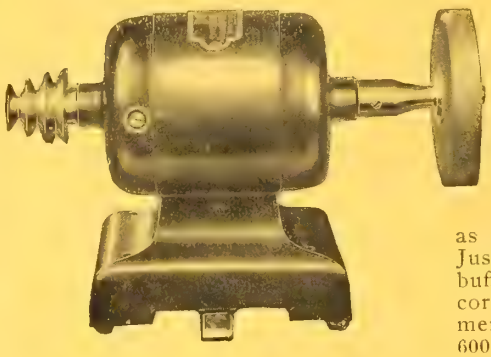
Satisfied to the extent of recommending the purchase of Wagner Quality Products to others. Please note this is not simply the OPINION of this customer, it is fact founded on the great teacher EXPERIENCE. Reliability, continuity of service, dependability, freedom from trouble or repairs—call it what you will—it is the most important factor TO YOU in the purchase of electrical apparatus.

Let us send you our handsomely illustrated Bulletin 11513, "Motor Applications."

Wagner Electric Manufacturing Company
of Canada Limited - Montreal

Northern Electric

"DUMORE" UTILITY MOTORS



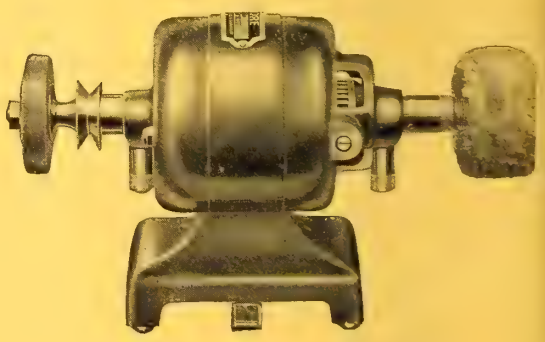
are a boon to Housewives, and go a long way towards helping solve the servant problem by furnishing sufficient power to do light chores. "DUMORE" Utility Motors are small in size but capable of long, hard service in driving many domestic appliances, or with attachments for polishing silverware, cleaning cutlery, sharpening knives, etc., etc.

TYPE "A" 1 25 H.P.

Built to meet the demand for a light, compact power unit. Finished in black enamel. Equipped with 3 ft. of cord and attachment plug, wheel arbor and emery wheel. Wheel arbor nickel plated. Speed 3000 to 9000 R.P.M.

TYPE "B" 1/25 H.P.

The Type B Motor is the same as the Type A illustrated above, excepting that it is finished in all nickel plate. Equipped with 3 ft. of cord and attachment plug Makes a very attractive looking motor for any use.



TYPE "C" 1/16 H.P.

Light and powerful. Always ready for use, and is as near trouble proof as it is possible to make a motor. Equipped regularly with 3-step pulley on one end of the motor shaft and a wheel arbor on the other, together with emery wheel. The Type "C" can be equipped the same as the Type "D" motor if so ordered. Just the motor for light polishing and buffing work. Equipped with 8 ft. of cord and attachment plug. Cutler-Hammer 3-speed Rheostat. Speeds 2000-6000-8000 R.P.M.

Practical—Efficient—Economical

For Jewelers, Dentists, Hotels and Restaurants the "DUMORE" Utility Motor will be found indispensable in a great many ways. Furnished in three sizes —"A"—1/25 H.P.; "C"—1/16 H.P., and "D"—⅛ H.P. For the benefit of the trade we have undertaken to advertise these famous "DUMORE" small motors to the public through the Daily Papers from coast to coast, and it will be to your distinct advantage to carry this line in stock for demonstration when called upon to do so.

For full particulars, prices and attractive literature, write our nearest house

TYPE "D" 1/8 H.P.

The Type "D" Motor is one of the most popular of stock sizes. Is especially adapted for jewelers' and dentists' work. Equipped with 8 ft. cord and attachment plug. Cutler-Hammer 3-speed Rheostat in the base. Shaft ends are tapered. Ritter chucks and wheel arbors can be used on this motor. Speeds 2000-6000-8000 R.P.M.

O-B Extruded Ear (Runner piece extruded metal. Malleable boss clinched and riveted on.)

On Round Wire Generous Amount of Metal in Lips

On Grooved Wire Perfect Wheel Clearance

On Figure 8 Wire Perfect Wheel Clearance

O-B Extruded Ears Will Save for You

There are five big reasons for putting O-B Extruded Ears on the trolley—denseness, toughness, ductility, accurate dimensions, uniformity.

All of these are natural consequences of the extrusion process which consists of forcing red-hot (not molten) brass through a die under tremendous pressure.

Because O-B Extruded Ears are so dense and tough they resist wear remarkably.

Because they are ductile and accurate in dimensions they fit the wire tightly and smoothly. So arcing is reduced materially.

Because they are uniform you can be certain that the long life you get from your trial installation is a true index of the saving you can make on the entire road.

Here is the surest, fairest way to find out what O-B Extruded Ears will save you — stagger them on the line with other ears and keep tabs on results. Write us about it.

Absorbs the Shock

Our special C. & H. Poly-Phase Meter is safe because it is fitted with new double terminal blocks that absorb the shock and reduce the danger of accident resulting from overloaded wires and from surge conditions during lightning storms.

This meter also has more inside room for the connections, and the three or four lines are carried straight through the meter from the left to right. In every respect this C. & H. Poly-Phase is a Safety Meter, and is undoubtedly the one to select for Installation on Long Distance Transmission.

C&H Poly-Phase The Safety Meter

The Company's guarantee goes with every instrument. The new Poly-Phase is as near perfect as it is possible for a meter to be.

THE "TYPE S" PORTABLE WHEATSTONE BRIDGE

Useful in the Shop and Laboratory for the Measurement of Resistance. Adapted for Fault Locations in Telegraph and Telephone Lines and Cables.

The Type S Bridge is a thoroughly practical instrument for shop and field use. Being complete in every detail it is ready at all times for immediate use. It is easily portable, its weight being but 8 pounds. The precision of adjustment of its coils (Rheostat 1/10 per cent., Ratio 1/20 per cent.) insures accurate measurements. The galvanometer, the weakest element of such an instrument, is unusually rugged. It is a separate element and may be removed for examination or repair by taking out two screws. The battery is of the ordinary "flash light" type, and renewals may be procured practically everywhere. The price is $66.25 net, f.o.b. Philadelphia, boxed for shipment.

Bulletin No. 530 describes this instrument.

The Right Start For a Profitable Resale Motor Business

With the arrival of his first order of R & M Motors, the dealer has made a start which will insure a healthy, permanent growth in his motor business.

The unfailing reliability and efficient operation of R & M Motors win friends for them wherever they are installed. Satisfied users and repeat orders can be counted upon as a certainty by the dealer who sells R & M Motors.

Their service records hold old customers for the dealer and permit him to concentrate his efforts on new prospects.

As a rule it is easy to get prospective users to try R & M Motors, too. This motor has been advertised dominantly in the leading magazines for a decade, and its reputation for reliability is pretty generally known everywhere—to prospective motor users as well as to experienced motor buyers.

The dealer who is planning for a permanent, growing motor business finds great value in the R & M policy of making good motors and keeping the public informed on them.

For individual room heating

The great economy problem this Fall and Winter will be the low cost of heating the home. Whether the present heating system is the old-fashioned coal heater or the modern hot water system it can be regulated to conserve fuel. But in doing this, all the rooms are not being properly heated.

The Hughes Electric Air Heater is an auxiliary heater which acts as a fill-in and makes this fuel conservation possible. The heat is instantly regulated to the requirement which makes it ideal for individual room heating. Portable, and can be moved from room to room—quickly warming it to a comfortable temperature.

Vol. 27 Toronto, October 15, 1918 No. 20

Continent's Total Water Power Insufficient for Present Demands

What may be considered the most valuable contribution to the year's literature on electrical progress, was the paper recently presented by Dr. C. P. Steinmetz, before the American Institute, on the general subject of energy, coal and water conservation. Dr. Steinmetz does more than deplore the rapid depletion of the continent's hard coal areas—he points a way to supplement them. And, first of all, he pricks that bubble of illusion of the oft-repeated statement to the effect that, after all, the coal doesn't matter so much—we have our water powers left. In answer to this, Dr. Steinmetz points out that if every drop of rainfall on this continent were caught and transformed into power, it would not be sufficient to take care of even the present day demands of our homes and industries, to say nothing of rapid and constant developments. At best our water powers, all of them put together, can merely be used as supplementary to our coal supply. The real source of energy to which we must look is the sun—and here, in the author's opinion, lies the hope of the distant future.

Dr. Steinmetz's suggestion for immediate conservation lies in the use of the induction generator. The present type of generating station is expensive, due to a multiplicity of the necessary regulating and protective equipment, which makes it impracticable to develop any but the largest and most favorably situated waterfalls. By the use of the induction generator the construction is greatly simplified and reduced in price and, as a result, water falls from 50 h.p. upwards could be utilized. By this arrangement the present system of distribution from large generators out along a network of lines to induction motors, would simply be reversed, and instead we should have a number of small induction generators feeding into a network of collecting lines. Small coal areas could be utilized in the same way.

The subject is treated from the standpoint of the citizen of the United States, but is no less interesting to Canadians on account of our dependance on U. S. coal. Canada's water powers, in proportion to our population, are greater than those of our neighbors, but much the same on the basis of area, and plainly we have nothing to give away or waste. It may be that the induction generator could be used to advantage on some of our smaller waterfalls or coal or oil fields, or possibly in connection with the utilization of our peat areas.

Disjointed Policy of City Regarding Toronto Street Railway

The operating situation on the Toronto Street Railway System has apparently become unmanageable from the company's standpoint and uncomfortable for the patrons. The plain fact appears to be that the company has not enough employees to man the cars, and has trouble with those it has. Quite recently an effort was initiated to train young women as conductors, but the "Union" threatened a strike and apparently the management have thought it best to drop the plan. Overcrowding at rush hours, both on the company and city lines, has reached a point where it hovers somewhere between bestiality and immorality and there is no evidence of relief in sight. The policy of the city as regards the street railway company is, and always has been, absolutely disjointed, so that the sum total of these spasmodic efforts is to embarass the company's operations.

There is little chance of improvement in conditions so long as no effort is made by the city authorities to advise themselves of the actual and adverse conditions under which the company is operating. While the two parties are continually at variance over even the smallest details, the service daily grows worse and the public bears all the inconvenience. The Toronto Railway Company know how to give a good service, because in former times it did so. All that is necessary, we believe, is the removal of the whole question from the political arena, and a capable committee to negotiate with the company. There can be no excuse for waiting. No one imagines or hopes that the city will be in a position to take over the system when the franchise expires. Why not settle the question of franchise now. Give the company some decent moral support and then see to it that they live up to their agreement. They will do it—willingly—if the city council will give them such assistance as will make it possible.

Another Private Power Project

Encouraged by the recent success of the St. Lawrence Power Company, the New York & Ontario Power Company has applied to the International Joint Commission for approval of its plans to construct a dam across the Little River on the South branch of the St. Lawrence, at Ogden Island. Canadian interests raise the objection that the dam would seriously affect navigation, and it is the intention of the government and the Dominion Marine Association to oppose the company's application.

The St. Lawrence River has enormous potentialities that should be developed in the most efficient and economical manner for future generations. The Canadian and American governments should keep the control of the river in their own hands. The war necessity plea of the St. Lawrence Power

Company cannot be urged in the case of the New York and Ontario Company.

The present power shortage in the Province of Ontario should convince the most skeptical that the water powers of the St. Lawrence River must be fully developed at an early date if our industries are not to suffer. This development must not be undertaken a piecemeal way, but according to a well-devised general plan, which will make the most of every available drop.

The alienation of little bits of power here and there threatens to make the larger development scheme impracticable and well-nigh impossible. It seems as if the time had arrived for the two Governments to get together, map out the whole plan of construction and initiate it forthwith either as a government enterprise or well-guarded concessions to private companies. No diversion of any water and no development work of any kind whatsoever should be considered for one moment, however, that is not a part of the general predetermined plan of the total final utilization of the river.

Canada's Grounds of Opposition.

The Dominion Government is opposing the company's application on the grounds that:

(1) It will interfere with the full and economic development of the St. Lawrence system as regards the navigation thereof and the power potentialities therein, which are common to both bordering countries and of equal advantage to each country.

(2) It will interfere with the complete regulation, by a dam at Canada Island, of the level and outflow of Lake Ontario.

(3) The future development of the river will necessitate the acquisition of any rights the applicant may have in the river, and the Government of Canada considers it inadvisable to create more.

(4) The St. Lawrence River has enormous potentialties that should be developed in the most efficient and economical manner for future generations. Such a piecemeal policy as proposed is not in conformity with this doctrine.

The Dominion Government claims also that original grantees' rights from the applicants' claim title have lapsed, and that the applicants, as successors, are now asking something entirely different from the privileges granted by the original acts of the Legislature of New York.

Montreal Electrical Luncheon

The Montreal electrical luncheon has made a promising start for the 1918-19 season. The opening meeting, on October 2nd, was well attended, the discussion being confined to the election of officers and committees, and to making arrangements for the season. Mr. W. H. Winter of the Bell Telephone Co. presided, and asked for such support as would make the luncheons a credit to the electrical fraternity of the city.

The following were elected members of the general committee:—Messrs. R. J. Beaumont, Shawinigan Water & Power Company; P. T. Davies, Southern Canada Power Company, Limited; W. J. B. Drew, Montreal Public Service Corporation; C. Duncan, Duncan Electrical Company, Limited; M. C. Gilman, Packard Lamp Company; A. S. Henry, Canadian Comstock Company, Limited; H. Hulatt, Grand Trunk Railway Telegraphs; L. A. Johnson, Northern Electric Company, Limited; J. McMillan, Canadian Pacific Ry. Co's. Telegraphs; W. P. Roper, Canada Wire & Cable Company, Limited; Wm. B. Shaw, Montreal Electric Company, Limited, and H. W. Wood, Canadian Crocker Wheeler Company, Limited. In addition to these, the members of the Finance, Luncheon, Papers, and Entertainment committees, whose names are given below, are members of the general committee.

The papers committee consists of Messrs. G. C. Read, (chairman), Montreal Light, Heat & Power Consolidated; P. A. McFarlane, Bell Telephone Company; J. A. Shaw, Canadian Pacific Railway Company, and G. E. Templeman, Electrical Service Commission; and the Luncheon Committee of Messrs. S. W. Smith, (chairman), Electrical Equipment Company, Limited, and A. J. Carroll, Eugene F. Phillips Electrical Works, Limited.

Mr. W. H. Winter was again appointed president, and Mr. T. H. Chennell re-appointed secretary-treasurer

The question of financing the luncheon was discussed at some length, the expenses being nearly $200. The old committee suggested that a fee of $2 be charged to those who desired to become regular members of the luncheon, although no one connected with the electrical industry would be debarred from attending. After several other suggestions had been made, the following were appointed to look after the financial arrangements, including contributions from the large electrical companies—Messrs. J. W. Pilcher, (chairman), Canadian General Electric Company, Limited; J. J. Sorber, Economy Fuse & Mfg. Co. of Canada, Limited; C. Thomson, Fred Thomson Company, Limited; and J. B. Woodyatt, Southern Canada Power Company, Limited.

The question of emphasizing the social side of the luncheons was brought up by Mr. Winter, and with this end in view it was decided to appoint a committee to make arrangements for one or more smokers. The following are the committee: Messrs. A. Dwight Smith, (chairman), Northern Electric Co. Limited; E. W. Sayer, Sayer Electric Co., and A. C. Towne, Dominion Lamp Company.

A vote of thanks was passed to Mr. E. N. Hyde, the chairman of last season's paper committee.

Montreal Tramways Company Gets Reasonable Treatment

In view of the heavy advance in the cost of operating street railways, the judgment of the Quebec Utilities Commission in the appeals of the Montreal municipalities against the decision of the Montreal Tramways Commission is of interest. The Utilities Commission varied that decision, but found that there is justification for higher fares. In what is known as the uniform tariff territory the fare is fixed at 6c or 5 tickets for 25c, with workmen's tickets at six for 25c, in place of 5c or 6 tickets for 25c, and 8 tickets for 25c, respectively, which were the old rates. The night tariff of 15c cash is an addition of 5c. Transfers are free. The Commissioners only slightly varied the decision of the Tramways Commission as to outlying districts, passengers going from the uniform tariff territory to these outside districts paying the city fare plus the fare in the outside municipalities. The company claimed a 7c fare or 4 tickets for 25c. in the uniform tariff territory with free transfers.

Under the contract of the city with the company, certain fixed charges have to be provided for, and the chief points at issue were as to the probable additional charges for maintenance and operation, which the company contended justified it in asking for a 7c fare. The Commission employed an accountant to check over the company's estimates, and he made an independent report upon the various items. The conclusion on the increased cost of material is that "sixty-one per cent of the average purchases to be made in 1918-19 will actually cost $423,884.60 more than they did in 1916-17, and that sixty-two per cent. of the average purchases to be made in 1918-19 will cost $189,965.09 more than 1917-18. As the sixty-one per cent. in 1916-17 amounted to $1,017,830.83, and the sixty-two per cent. in 1917-18 to $1,-

424,894.73, the percentage of increase is somewhat startling, being roughly 42 and 13, respectively."

The Commission estimated the revenue under the old schedule at $7,625,000, and the expenditure at $9,249,407, including interest on $36,286,295, the capital of the company, as valued by the Tramways Commission. This would leave a deficit of $1,624,407—and "manifestly it is, under these circumstances, impossible to maintain present rates." The new tariff is estimated to yield $9,363,094, to meet expenditure of $9,343,038, the latter sum including $93,630 for the annual contribution to the contingent fund, not reckoned in the first named estimate of expenditure.

"The margin between revenue and expense is very small and we are not averse that it should be so. We are dealing with a time of abnormal scarcity and high prices, not one in which to accumulate a reserve. Under the terms of the contract the interests of the shareholders and of the city of Montreal as a corporation are quite sufficiently protected, and the accumulation of a surplus can be left to a more favorable opportunity. As it is, the contract leaves us no option in the matter of making the revenue meet the expense of operation and maintenance. We have done this to the best of our ability and, in our opinion, we should not be justified in doing any more."

The new fares are now in operation, and the company has also altered the old transfer system, by punching on the transfers the point at which the passenger desires to change cars. Hitherto passengers were able to transfer at any point along the route without designating that point when boarding the car.

The report of the Montreal Tramways Co. for the year ended June 30th, indicates that the surplus was drawn on to the extent of $303,991, it now standing at $552,457. The total earnings were $5,526,796, and the expenses $5,830,787, this sum including three quarterly dividends of 2½ per cent., the one due August 1st having been deferred.

Toronto Section A. I. E. E.

The programme at the October 4th meeting of the Toronto section of the A.I.E.E. took the form of a discussion on the subject: "The Grounded Neutral."

Mr. W. P. Dobson, in opening the discussion, outlined the different methods of operation of h.t. lines, showing that important and extensive systems were working with dead ground, resistance ground, ungrounded star and delta connections with evident satisfaction.

Mr. P. Ackerman dealt with the advantages of the isolated neutral covering both Y and delta systems. Possibility of maintaining operation with one line grounded was of value.

Mr. H. C. Don Carlos was strongly in favor of a ground with moderate resistance on h.t. lines as yielding less strain on the insulation, but preferred the delta connection for distribution work. The grounding resistance results in less mechanical strain on the generators and transformers; he believes that a reactance shunted by a high resistance would form the ideal ground connection. The Central Ontario system had been operating some years with isolated Y, but it was intended to ground in the near future to save the insulators, which were showing signs of fatigue.

Mr. W. G. Gordon gave an interesting account of the results from arcing grounds on an ungrounded system with a theoretical consideration of the frequencies and voltages possible under various conditions of resonance, etc.

Mr. A. J. Jones (Niagara Falls Power) is about to ground a 22,000 volt. system, after running isolated for some years. It was found that a circulating current of 800 amps. was flowing between their Westinghouse and G. E. generators, but none between machines of the same make. Ground resistance of 3 ohms. was proposed.

Mr. O. V. Anderson claimed that a distribution system is subject to the same laws and reasoning as a transmission system and grounding in both cases provides continuity of service by locating trouble as soon as it occurs, which is a much greater advantage than the possibility of operating during a fault. The only case of telephone interruption in his experience was found to be due to a bad ground on the telephone company's own system.

Mr. D. A. McKenzie favored dead ground under all conditions; the use of a resistance does away with the good effect of the ground connection. The strain on transformers would certainly be obviated by the reactance of the lines in a large system.

Mr. A. L. Mudge was strongly of the opinion that there is room for difference of judgment in the matter of grounding. For a typical small system of 20,000 kw. 22,000 or 44,000 volts, supplied by a single generating station, ungrounded Y would be preferred. Some initial trouble had been obviated by grounding.

Mr. E. J. T. Brandon showed that the costs of equipment on a delta system were higher than with a grounded Y.

Mr. F. T. Wyman stated that the cost of the main transformer would show small disparity. In any case a ground connection should have a resistance or reactance to take the strain off the transformer. In some cases transformers broke down, due to the fact that the whole line voltage was thrown on the first few turns causing stresses which no transformer would be expected to carry.

Mr. J. B. McCarthy (Can. Copper Co.)—On a 60 mile, 33,000 volt. line delta—delta connection found to be quite o.k.; some poles had been burnt, but the fact of its being a wood pole line helped to keep the load on in case of a short.

Mr. H. B. Dwight believed the problem to be one of operating voltage. Below 60,000 v. it might be all right to operate with isolated neutral.

Mr. P. Ackerman was of the opinion that ground resistance should be as low as possible; preferably nil. It has no draining off function because this is effected by the lightning arresters. As to the strain on transformers, they should be designed to carry a short circuit to ground in any event.

Mr. R. W. Osborne pointed out that while ordinary frequency occasions no disturbance on telephone lines the higher harmonies induced on the h.t. lines do cause trouble and therefore grounding is more necessary on h.t. than on l.t. systems.

Messrs. P. A. Borden and R. R. Stevenson also spoke briefly.

The Electric Club of Toronto

The Electric Club of Toronto held two more successful luncheons on September 27 and October 4. On the former Friday Mr. Walter Chapman, the well-known architect, was the speaker on "Architecture." On Friday, October 4th, Mr. J. A. D. McCurdy, Canada's pioneer airman, described the evolution of the aeroplane beginning with the earliest history of the "gliding" machine, up through the controversy between the "heavier than air" and "lighter than air" advocates, to the present day. The members were specially pleased to have with them on this occasion, also, Mr. McFarlane, the president of the Bell Telephone Company, who spoke briefly.

The Energy Supply of North America

Dr. Steinmetz Before the A.I.E.E. urges the Conservation of Coal and the Utilization of all Possible Water powers—The Supply of Both is Limited

The only two sources of energy which are so plentiful as to come into consideration in supplying our modern industrial civilization, are coal, including oil, natural gas, etc., and water power.

While it would be difficult to estimate the coal consumption directly, it is given fairly closely by the coal production, at least during the last decades, when wood as fuel became negligible; and export and import, besides more or less balancing each other, were small compared with production. Coal has been mined since 1822, and in Table 1 is recorded the coal production of the United States, from governmental reports—the decennial averages in millions of tons per year.

Table I.

Average Coal Production of the United States.

Year	Million tons	Percent increase per year
1825	0.11	
1830	0.32	22.4
1835	0.83	19.7
1840	1.92	17.0
1845	4.00	14.5
1850	7.46	10.45
1855	10.8	8.35
1860	16.6	8.72
1865	25.9	9.22
1870	40.2	8.58
1875	56.8	7.42
1880	82.2	7.95
1885	122	6.80
1890	160	5.40
1895	206	5.75
1900	281	6.96
1905	404	6.60
1910	532	

Estimating the chemical energy of the average coal as a little above 7,000 calories, the chemical energy of one ton of coal equals approximately the electrical energy of one kilowatt-year (24-hour service). That is, one ton of coal is approximately equal in potential energy to one kilowatt-year.

Thus, the annual consumption of 867 million tons of coal (estimate of this year's production) represents in energy 867 million kilowatt-years. However, as the average efficiency of conversion of the chemical energy of fuel into electrical energy is probably about 10 per cent, the coal production would be able, if converted into electrical energy, to give about 87 million kilowatts.

Assuming, however, that only one half of the coal is used for power, at 10 per cent efficiency, the other half as fuel, for metallurgical work, etc., at efficiencies varying from 10 to 80 per cent, with an average efficiency of 40 per cent, we get in electrical measure 217 million kilowatts (24-hour service) as the total utilized energy of our present annual coal production of 867 million tons.

Potential Water Powers of the United States

Without considering the present limitation in the development of water powers, which permits the use of only the largest and most concentrated powers, we may try to conceive the total amount of hydraulic energy which exists in our country, irrespective of whether means have yet been devloped or ever will be developed for its complete utilization. We then proceed from the estimation of the energy of the total rainfall.

The total rainfall of the North American continent between 30 and 50 degrees latitude represents 3000×10^{15} kg-m. This equals 950 million kilowatt-years (24-hour service). That is, the total potential water power of the United States, or the hydraulic energy of the total rainfall, from the elevations where it fell, down to sea level, gives about 1000 million kilowatts.

However, this is not available, as it would leave no water for agriculture; and, even if the entire country were one hydraulic development, there would be losses by seepage and evaporation.

An approximate estimate of the maximum potential power of the rainfall, after a minimum allowance for agriculture and for losses, (in this, 12.5 cm. rainfall has been allowed for wastage, and 25 and 37.5 cm. respectively, for agriculture, where such is feasible) gives as total available potential energy about 1200×10^{15} kg-m., or 380 million kilowatts (24-hour service).

Assuming now an efficiency of 60 per cent from the stream to the distribution centres, there remain 230 million kilowatts (24-hour service) as the maximum possible hydroelectric power which could be produced if, during all seasons, every river, stream, brook, or little creek throughout its entire length from the spring to the ocean, together with all the waters of the freshets, could be and were used. It would mean that there would be no running water in this country; in fact, there would be only stagnant pools connected by pipe lines to turbines exhausting into the next lower pool. Obviously, we could never reasonably hope to develop more than a part of this power.

It is interesting to note that the maximum possible hydraulic energy of 230 million kilowatts is little more than the total energy which we now produce from coal, and is about equal to the present total energy consumption of the country including all forms of energy.

This is rather startling. It means that the hope that when coal once begins to fail we may use the water powers of the country as source of energy is and must remain a dream; for if to-day all the potential water power of the country were developed and every rain drop used it would not supply our present energy demand.

Thus hydraulic power may and should supplement coal as a source of power, but can never replace it.

This probably is the strongest argument for efforts to increase the efficiency of our means of using coal.

Solar Radiation.

The source of energy, which is practically unlimited, if it only could be used, is solar radiation. Estimating the solar radiation at the earth surface as 1.4 calories per sq. cm. per min. would give, per sq. cm. horizontal surface between latitudes 30 and 50, assuming 50 per cent. cloudiness, an average throughout the year (24 hours per day) of about 0.14 calories per sq. cm. horizontal surface per min. and on the total area of North America, between 30 and 50 latitude, 8.3 million square kilometres, a total of approximately 800,000 million kilowatts (24-hour service)—a thousand times as much as the total chemical energy of our coal consumption,

or 800 times as much as the potential energy of the total rainfall.

Considering that the potential energy of the rainfall—from surface level to sea level—is a small part of the potential energy spent by solar radiation in raising the rain to the clouds, and that this is a small part of the total solar radiation, the foregoing is reasonable.

Considering only 2.7 million square kilometers, which are assumed as unsuited for agriculture, and assuming that, in some future time and by inventions not yet made, half of the solar radiation could be collected, this would give an energy production of 130,000 million kilowatts.

Thus, even if only one tenth, or 13,000 million kilowatts, of this could be realized, it would be many times larger than all the energy of coal and water power. Here then would be the great source of energy for the future.

Hydro-electric Stations—The Modern Synchronous Generator Station.

In developing the country's water powers, thus far only those of greatest energy concentration have been considered, that is, those where a large volume and a considerable head of water were available within a short distance.

This led, as the best solution for the problem, to the present type of hydro-electric generating station. Due to the high powers controlled by these stations, the auxiliary and controlling devices have become so numerous as to make the station a complex structure requiring high operating skill and involving high cost of installation.

Not only are all these devices necessary for the safe operation of the station, but at the same time it must be expected that, with the further increase of power of our electric systems, additional devices will become necessary for safe and reliable operation. One such device is the automatic recording apparatus, such as the multi-recorder.

With this type of station it obviously is not possible, in most cases, to develop water powers of small and moderate size, and a generating station of a thousand horse power will rarely, or one of a hundred horse power hardly ever, be economical.

On the other hand, a hundred horse power motor installation is a good economical proposition, and the average size of all the motor installations is probably materially below one hundred horse power.

It is startling to see how large a part of the potential water power of the country is represented by relatively small areas of high elevation, in spite of the relatively low rainfall of these areas. As most of these areas are at considerable distances from the ocean, most of the streams are small in volume. That is, it is the many thousands of small mountain streams and creeks, of relatively small volume of flow but with high gradients affording fair heads, which apparently make up the bulk of the country's potential water power.

Only a small part of the country's hydraulic energy is found so concentrated locally as to make its development economically feasible with the present type of generating station. Therefore some different and very much simpler type of generating station must be evolved before we can attempt to economically develop these many thousands of small hydraulic powers, and collect the power of the mountain streams and creeks.

Simplification of the Hydro-electric Station.

The following discussion of the simplification of the Hydro-electric station to adapt it to the utilization of smaller powers is limited to the case where smaller hydraulic stations fed into a system containing some large hydraulic sta- steam-turbine stations from which the system may be controlled.

We may eliminate the low-tension busbars, with generator circuit breakers and transformer low-tension circuit breakers, and connect each generator directly to its corresponding transformer, making one unit of generator and transformer, and do the switching on high-tension busbars which, with the circuit breakers, can be located outdoors. While it is dangerous to transformers to perform the switching on the high-tension side, due to the possibility of cumulative oscillation, this danger is reduced by the permanent connection of the transformer to the generator circuit, and is less with the smaller units used in small power stations, and therefore permissible in this case. However, the simplification effected is pronounced, since ammeters, voltmeter and synchronizing devices with their transformers are still retained on the low tension circuits.

Since it is not economical to operate at partial load, proper operation of a hydraulic station on a general system requires that as many units operate fully loaded as there is water available for, and to increase or reduce the number of units (of turbine, generator, and transformer, permanently joined together) with the changing amount of available water, thus using all the energy of which the water is capable.

In this case the turbine governors, with their more or less complex hydraulic machinery, may be omitted. If then the generators are suddenly shut down by a short circuit which opens the circuit breakers, the turbines will race (run up to their free running speed) until the gates are shut by hand. However, generators and turbines must be able to stand this as even by the use of governors the turbines may momentarily run up to their full speed, in case of sudden opening of the load, before the governors can cut off the water. Where this is not desirable, some simple excess speed cut-off may be used.

When eliminating the governing of turbines and running continuously at full load, the question may be raised whether generator ammeters are necessary, as the load is constant and is all the power that the water can give. With synchronous generators, however, the current depends not only on the load but also on the power-factor of the load, and with excessively low power-factor due to wrong excitation the generators may be overheated by excess current, while the power load is well within their capacity. Thus ammeters are necessary with synchronous generators. As soon, however, as we drop the use of synchronous generators and adopt induction generators, the ammeters with their current transformers may be omitted, since the current and its power-factor are definitely fixed by the load. At the same time, synchronizing devices, together with potential transformers, generator voltmeters, etc., become unnecessary. A station voltmeter may be retained for general information but is not necessary, as the voltage and frequency of the induction generator station are fixed by the controlling synchronous main station of the system.

With the adoption of the induction generator the entire exciter plant is eliminated, as the induction generator is excited by lagging currents received from synchronous machines, transmission lines, and cables existing in the system. Thus are dispensed with the exciters, exciter buses, ammeters, voltmeters, alternator field rheostats, etc.; in short, most of the auxiliaries of the present synchronous station become unnecessary.

Thus, **the solution of the problem of the economic development of small water powers is found in the adoption of the induction generator.**

Stripped of all unnecessaries, the smaller hydro-electric station would comprise:

Hydraulic turbines of simplest form, continuously operating at full load, without governors.
Low voltage induction generators directly connected to the turbines.
Step-up transformers directly connected to the induction generators.

High-tension circuit breakers connecting the step-up transformers to the transmission line. In smaller stations, even these may be dispensed with and replaced by disconnecting switches and fuses.

Lightning arrester on the transmission line, where the climatic or topographical location makes these necessary.

A station voltmeter, a totaling ammeter or integrating wattmeter and a frequency indicator may be added for the information of the station attendant, but are not necessary, as voltage, current, output, and frequency are not controlled from the induction generator station, but from the main station, or are determined by the available water supply.

It is interesting to compare this induction generator station lay-out with that of the modern synchronous station. However, it must not be forgotten that **the simplicity of the induction generator station results from the transference of all the functions of excitation, regulation, and control to the main synchronous stations of the system,** and thus the induction generator stations are feasible only as adjuncts to at least one large synchronous station (hydraulic or steam turbine) in the system, but can never replace the present synchronous generator stations in their present field of application.

Automatic Generating Stations.

With the enormous simplification resulting from the use of the induction generator it appears quite feasible to make smaller hydroelectric generating stations entirely automatic, that is, operating without attendance beyond occasional (weekly or daily) inspection.

Such an automatic generating station would comprise a turbine with low-voltage induction generator housed under a shed, and an outdoor step-up transformer conected into the transmission line with time fuses and disconnecting switches.

It is true that in the big synchronous generating stations of thousands of kilowatts, the cost of auxiliaries, such as exciter plant, regulating and controlling devices, etc., is only a small part of the total station cost, and little would therefore be saved by the use of induction generators. No induction generators would, however, be used for such stations. But the cost of auxiliaries and controlling devices, and the cost of the required skilled attendance decrease far less with decreasing station size than that of the generators, whether synchronous or induction, or, in other words, with decreasing size of the station **(per kilowatt output)** the cost of auxiliaries and controlling devices, and of attendance, increases at a far greater rate than that of the generators, and very soon makes the synchronous station of the present type uneconomical.

It is also true that in the big modern hydraulic power systems, the cost of the generating station usually is a small part of the cost of the hydraulic development. Therefore, any saving in the cost of the generating station would be of little influence in determining whether the hydraulic development would be economical. With decreasing size of the water power the cost of the hydraulic development **per kilowatt output** usually increases so rapidly as to very soon make the development of the water power uneconomical, no matter how simple and cheap the station is.

Value of the Induction Generator.

However, the value of the induction generator lies not so much in the reduction of the cost of the generating station as in the reduction of the cost of the hydraulic development, through making it possible to apply to the electric generator the same principle which has made the electric motor economically so successful. **Collect the power electrically just as we distribute it electrically.**

We do not, as in the days of the steam engine, convert the electric power into mechanical power at one place by one big motor and distribute it mechanically by belts and shafts; but we distribute the power electrically, by wires, and convert the electric power to mechanical power, wherever mechanical power is needed, by individual motors throughout mill and factory.

In the same way we must convert the hydraulic, that is, the mechanical power, into electrical power by individual generators located along the streams or water courses within the territory, wherever power is available, and then collect this power electrically by medium-voltage collecting lines and high-voltage transmission lines, and so eliminate most of the cost of the hydraulic development, to solve the problem of the economical utilization of the country's water powers. If we attempt to collect the power mechanically, that is, by hydraulic development which gathers the waters of all the streams and creeks of a territory together into one big station and there converts it into electric power, the cost of the hydraulic development makes it economically hopeless except under unusually favorable conditions where a very large amount of power is available within a limited territory, or where nature has done the work for us in gathering considerable power at a waterfall, etc.

It is the old problem and the old solution: If you want to **do it economically, do it electrically.**

Naturally then, we would use induction generators in these small individual stations, just as we use induction motors in individual motor installations, but, where large power is available, there is the field of the synchronous generator, where the induction generator is undesirable, just as the synchronous motor is preferable where large power is required—unless the synchronous motor is excluded by conditions of starting torque, etc.

At first, and for some time to come, we would not consider going down to sizes of induction generators anywhere near as small as are common in induction motors. However, throughout the country, there are undoubtedly many millions of kilowatts available in water powers which can be collected by induction generator stations from 50 horse power upwards, and which at fair heads, would require no abnormal machine design (no very slow speed).

Consider the instance of a New England river with a descent in its upper course of about 1,100 feet of varying gradient within five miles: at three places where the gradient is steepest, by a few hundred feet of cast-iron pipe and a small dam of 20 to 30 feet length and a few feet height (just enough to cover the pipe intake), an average head of 150 feet can be secured, giving an average of 75 horse power each, or a total of 225 horse power or 170 kilowatts. This would use somewhat less than half the total potential power. The development of the other half, requiring greater length of pipe line or involving lower heads, would be left to meet future demands for additional power.

The installation of an electric system with 170 kilowatts would hardly be worth while; but there are numerous other creeks throughout the territory from which to collect power and which within a few miles pass high potential transmission lines, coming from big synchronous stations into which the power-collecting lines from the induction generator stations could be tied and from which they could be controlled.

Thus, the large modern synchronous station has its field and is about as perfect as we know how to build stations for large concentrated powers; but beyond this there is a vast field and therefore an economic necessity for the development of a different type of hydraulic generating station to collect the scattered water powers of the country, and that is the induction generator station, to which it is desired to draw attention.

Caution must be exercised, however, not to mistake small power and low-head power. There are, on the lower courses of our streams, some hydraulic powers which are relatively

(Concluded on page 38)

Big Japanese Electrical Exhibition

Shows Possible Markets and Competition to be Expected—A Country Wide Awake to After War Needs and Preparing to Meet Them

One of the finest and most creditable exhibits illustrative of any industry in Japan was that lately held at Uyeno Park, Tokyo, by the Japan Electrical Society in commemoration of its twenty-fifth anniversary. To one not acquainted with the rapid progress made in all lines of industry in this country, the exhibtion just closed would come as a surprise. When we remember that up to thirty years ago electric energy was never used in Japan, other than the weak current necessary for telegraph and telephone lines, it is all the more remarkable to witness specimens of almost every known electric device. The use of electricity has become very widespread during the last twenty years, as may be judged by the number of electric-lighting companies in Japan, which in 1915 exceeded 485, using 8,400,000 lamps, or by the number of electric motors in use, which amounted in 1915 to 42,000 in number, developing 182,704 horse-power, and also by the electric tram lines, which totalled 71 in number in 1915, with an aggregate total mileage of over 1,285 miles. During the last three years still greater advancement has been made, but the figures for these years have not as yet been officially announced.

Object of Exhibition.

In 1896 the Japan Electrical Society was formed for the purpose of promoting electrical science and industry. During the last twenty years this society has been very active in its propaganda and has been successful in its aims, so much so that to-day there is hardly a family in any of the cities and towns of Japan which does not know some at least of the many advantages to be derived from electric energy. Furthermore, since the outbreak of war in Europe this society has been able to direct its efforts towards greater progress in peaceful pursuits, while the Allies have been wholly taken up with the affairs of war. It has been this peace footing that has therefore helped the electrical industry of Japan to make sure its foundation of success, and to prepare accordingly for the great competition that will surely break once peace is declared.

With the further intention of strengthening the position of electrical enterprises in this country, the Japan Electrical Society decided to open an extensive electrical exhibition which would embody all the representative branches of the industry.

General Plan of the Exhibit.

From the first announcement of this exhibition, applications poured in from electrical industries all over Japan. In order to give each exhibit sufficient space to make a creditable showing it was decided that it would be best to only allow a limited number of firms to exhibit their goods. The management with this end in view, could only accept the first 227 applications, those who applied late having to be declined on account of lack of space. On the average the allotment to each exhibit amounted to 7 tsubo or about 28 square yards; some of course were much larger and others smaller.

Classification of Exhibits.

The exhibts were divided into thirteen classes, as follows:—

Class 2.—Electro-chemical industry: Electrolysis, electric and utensils, toilet sets, cleaning utensils, stoves and furnaces, laundry appliances and fittings, electric fans, small electric motors, their appliances, electric bells and indicators.

Class 2.—Electro-channel industry: Electrolysis, electric furnaces, machines, apparatus and tools relating thereto, their products.

Class 3.—Electrical communications: Telegraphs, telephones, electric signals, etc.

Class 4.—Electric illuminations: Electric lamps, materials used for the fabrication of lamps, shades and globes; electric illumination appliances, electric advertisements, etc.

Class 5.—Generation and distribution: Generators, transformers, switchboards, conducting wires, cords, connecting appliances, meters, lightning rods, switches.

Class 6.—Application of electric current: Motors and appliances, devices for the application of the electric current.

Class 7.—Electric vehicles: Electric automobiles, aeroplanes, motor-boats.

Class 8.—Electricity and agricultural, mining and fishery industries: Machines used in mining, machines and farm implements used in agriculture, fittings and tackle used in fisheries, etc.

Class 9.—Development of electricity.

Class 10.—Materials used in electric industry.

Class 11.—Electro-physical and chemical apparatus, electric medical appliances: Physical and chemical apparatus, medical and surgical apparatus and appliances.

Class 12—War and electricity: Ordnance, war requisites with the application of electricity.

Class 13.—Government and school exhibits, etc.

Unfortunately these classes were not adhered to very strictly in arranging the layout of the exhibition. Thus we might see a demonstration of cooking utensils in four different buildings mixed up with other varieties of electrical supplies. If each class of goods could have been shown together the exhibition would not have seemed nearly so complicated in the minds of the general public.

A Typical Building.

A typical exhibition was that of a large Japanese electrical and engineering works. Here were demonstrations of the use of electricity as applied to industrial and household work. A large horizontal electric crane was seen travelling up and down. Attached to this was a powerful magnetic lift which demonstrates how iron and steel rails may be picked up and loaded into cars with a magnet. In one corner of the building was a small model of an up-to-date electric shipyard derrick with similar magnetic lift attached. Then again many different kinds of motor and motor machinery such as electrically driven lathes, milling machines, drills, planers, etc., were all in operation for the benefit of the public. In another part of this building was a display of switchboards, together with a model elevator, while in yet another were many kinds of household utilities such as electric heaters, irons, hot water bags, laundry machines, ice-cream freezers, etc.

Electric Stoves.

The first exhibit to be seen in the eastern pavilion was that of an Osaka concern who were showing electric cooking stoves and heaters for household purposes. Most of the stoves shown were intended for Japanese use, being only a

By A. E. Bryan, Canadian Trade Commissioner at Yokohama.

... and a half high, as the Japanese of course, cook sitting on the "tatami" (Japanese floor). There were one or two foreign models on display also. One style with two ovens, and two large and two small cooking plates sold retail for yen 450. Compared to Canadian electric stoves the above model was inferior both in workmanship and in design. It was said that the Japanese have not been able as yet to manufacture electric cooking stoves of the same quality as those of Canadian origin, nevertheless they are to be complimented on the progress they had made in this direction, for the electric stove industry is only in its infancy here. It stands to reason that improvement will be made on cooking stoves, as has been done on other electric devices which are now made to perfection in this country.

Of much interest were the electrified Japanese hibachi which were in display here and in other exhibits. This Japanese stove is really a wooden box or a round bowl-shaped container which is filled with charcoal ashes nearly to the top. In these ashes charcoal is burned and it is upon this that the ordinary Japanese family cooks its meals and secures its heat in cold weather. Instead of the charcoal, the electric hibachi have an electric coil operated on the same principle as are electric toasters. On account of the present high prices of charcoal, the new electric stove ought to prove very popular amongst Japanese families in towns and cities where nearly all have electric light installed in their homes.

Electric Insulators.

Another interesting display in this pavilion was one advertising porcelain insulators; a strong current was made to pass a spark six or eight inches long from brass wires projecting from porcelain insulators which passed in succession under a main wire, illustrating the efficiency of the insulation. The sight of this big spark was very interesting to the public and drew crowds of spectators.

There were many interesting exhibits showing other various kinds of insulating materials made from ebonite, mica, asbestos, caoutchouc, rubber electric cables, marble, etc. Each was represented by a company specializing wholly in that particular insulator. The asbestos booths were particularly interesting in that samples of Canadian asbestos were on view along with Russian, African, and Italian asbestos.

Turbines.

There were many exhibits of turbines of various forms from the ship turbine to the water turbine used in power-houses.

Wire Cables.

What were considered to be the best displays in the whole exhibit were those of the wire cable manufacturers. It is remarkable what Japan has accomplished in this industry. Plain copper wires, copper belts, armoured cables of all descriptions, flexible copper wires, transmission wire, electric bell wire, telephone and telegraph wire, asbestos-covered wires and patent non-sulphur resistant rubber wires were all shown on a most elaborate scale. Japan being one of the greatest copper-producing countries in the world, has everything in its favor for the manufacture of copper wire of all kinds. One or two of the exhibitors had displays of wire arranged according to the countries to which the wire was exported, showing that these firms were shipping electric wire practically all over the world. Most of the wire manufacturers also showed brass products such as piping, tubes, sheets, plates, etc.

Motors and Generators.

There were many splendid displays of electric motors of all kinds. Probably it would be safe to say that there were more motors than any other electrical machinery on exhibit, in one form or another.

Electric Lights.

Three good exhibits of electric light bulbs of various sizes and description were on view, and one company showed the whole process of manufacture from the glass bulb to the finished light. Other firms were showing electric sockets and light fixtures, shades, etc.

Telephone and Telegraph Instruments.

There were six firms showing exhibits of communication apparatus of various kinds, three of which represented telephone manufacturers and three telegraph and wireless telegraph makers. The telephone has been in great demand during the last two years and many have been manufactured. So far the Post and Telegraph Departments, which control the telephone system, have not been able to cope with the demand. In Yokohama this month there were applications for four thousand telephones, while the authorities could only allot some one hundred and fifty new telephones, which are being distributed by a process of drawing by lot—those who draw the right number will get telephones.

The wireless telegraph displays were very well arranged. Not only were there instruments inside of the pavilions, but there was set up outside of the buildings a wireless plant which was sending and receiving messages during the whole of the exhibition.

One is amazed on first arriving in Japan, with the number of wireless outfits that can be seen, when travelling through the country, amateur outfits located in some back-yard perhaps, as Japanese boys take a great interest in wireless telegraphy which accounts in part for its popularity in this country.

Transformers

Eight displays illustrated the transformer industry in this country—from the little common variety that one sees on the telegraph poles up to the large power-house size—eight and ten feet high.

Dry and Wet Batteries and Appliances.

There were seven different displays of batteries—from the pocket flash light variety to the large storage batteries used for lighting automobiles, houses, etc. Pocket flash lights of different varieties were usually on display also.

Miscellaneous Electric Devices.

Other interesting displays were staged representing the following: Automatic signals for electric cars, motor fans, laundry machines, electric furnaces for baking china and porcelain ware, elecric volt motors, tachometers, speed indicators, electric pumps, electric rice cleaning mills, magnetos, electric automobiles, electric clocks and electric pumps of every description.

Electric Railway Models.

Besides the models of electric cars which were shown illustrating their mechanical workings, etc., the Imperial Government Railways had a very attractive exhibit showing dining, sleeping and other cars, as used on their lines. There was also on display the first street car ever run on the streets of Tokyo.

Surgical and Medical Supplies

Modelled after German designs, the exhibits of surgical and medical apparatus presented a very attractive appearance. There were in all eight companies represented in this class. To the layman the X-rays and various massage instruments and healing appliances all looked to be equal of those seen in other countries.

University Exhibits.

Besides those displays shown by each individual manufacturer, the universities of Japan each contributed a booth

where some particular electric device as used for the instruction of students, was shown. Thus the Waseda University were exhibiting a vacuum discharge apparatus, the Imperial University sets of anemometers, direct current dynamos, high tension insulators, and electro-therapeutic machines, etc., while the Tokyo Technical School had on view a three-horse power reduction motor, besides transformers, etc.

Government Exhibits.

The various departments of the Japanese Government displayed very interesting examples of the utility of electricity.

The Naval Department had on view a very powerful search-light such as is used on warships. A late model of an anti-aircraft gun was also demonstrated with particular reference to the electric motor controlling its movements. The War Department showed some up-to-date army wireless outfits together with telescopic searchlights, etc. The Department of Communications exhibited various kinds of telegraph instruments, wireless apparatus and fittings therefor.

The Korean Government had an exhibit showing the kind of telegraph and telephone system in vogue in that country. While the Imperial Government Railway of Japan and the Manchurian Railway Company each has interesting exhibits of passenger cars as used on these railways, and showed also the illuminating systems therein.

Associate Electrical Products.

There were also some fine exhibits of products made by the use of electricity or articles used in addition to electricity for the manufacture of some other commodities. Five exhibits illustrated the calcium carbide industry, the carbide was shown packed ready for shipment in steel drums which were inserted in a wooden case. Electric steel made in Japan was exhibited by five different companies. Carbon electrodes from the smallest to the largest sizes were on view in three different booths—other products which attracted one on passing through the various pavilions were—carbon brushes, caustic soda, bleaching powder, potassium chloride, electro-chemistry apparatus, ferrochrome and ferro-silicon, ammonium sulphate, zinc paints, electric soldering machines, cement, metallic tungsten and oxides, antimony, electric hair dressing requisites, and electro-plated wares such as cutlery of all kinds, spectacle frames, etc. An electric incubator was also demonstrating its ability to hatch out young chickens before the eyes of many eager onlookers.

Model of Hydro-Electric Power Plant.

Probably the best arranged demonstration of any seen at this exhibtion, as well as the most creditable to the management, was the modelled hydro-electric system which was built up on one side of the exhibition grounds.

An artificial mountain fifty feet high, the foundation of which covered about 3,540 square yards of land, was built up with structural timbers, and covered with soil, rocks, turf, trees and flowers in order to give it the appearance of a real mountain, with all its natural appearances. Along the top of this structure and at a slight decline ran an artificial river, the head of which was really supplied with water by a motor and pump, but the scenic effects of which gave the appearance of a great lake out of which the stream wound its way among rocks and ravines, all very natural in appearance, to the head of the pipe that took it down to the turbine or horizontal water wheel of Pelton tpye, constructed by one of the exhibitors, and which developed a force of 150 horse-power. This water wheel was constructed with glass sides so that the spectators could see the inward workings of the machine. There was a dynamo connected with this water wheel, and the electricity generated was then transformed by means of three transformers to a higher tension and distributed throughout the exhibition grounds to supply the current needed for the many lights, search-lights, etc., which were lit up in the evenings.

Over this mountain and through the grounds high voltage wires were carried on steel frames, very similar to those in use by the Ontario Hydro-Electric Commission, but which were entirely constructed in this country.

A tunnel eighty-four feet in length ran through the centre of this artificial mountain, and inside of which were scenes depicting actual conditions of warfare on the Western Front. There were also paintings by a famous Japanese artist.

Electric Searchlights.

Each evening after dark a battery of thirteen powerful searchlights situated on the top of the north pavilion, which were provided by the Naval Department, would play on the surrounding country and cast great streams of light on the sky and on the lake Shinobozu. This was a unique sight for the public of Tokyo and was very attractive.

Model Suite.

One exhibit which proved very popular was the model Japanese suite of five or six rooms fitted up with all the possible electrical fittings that could be applied to a house, such as electric stove, kettle, fan, lights, bath-tub heater, toasters, irons, etc. This served as a demonstration for the Japanese public in making their house comfortable and at the same time was an advertising medium.

Reinforced Concrete Appliances.

One firm had a very interesting exhibit of concrete products as applied to electrical conveniences. A few samples of concrete double-track trolley line poles were on view, while there were also railway sleepers made of reinforced concrete.

Tokyo Educational Association.

This association had a booth fixed up in the form of a laboratory where there were about twelve microscopes as well as many different kinds of electrical toys and novelties such as buzzers and shockers, which the general public were privileged to use.

Why Not Conserve Jitney Gasoline?

While we have no fault to find with the fuel administrator for establishing chugless Sundays if the needs of the government for gasoline require them, and we accept his word for this, we invite his attention to another way in which he can stop the unnecessary use of a large amount of gasoline. We refer to the suppression of jitneys, for whose waste of gasoline, rubber, and lubricating oil, all necessary to our military forces, there is no economic excuse. Such action by the fuel administrator would correct a manifest evil so far as the consumption of these war essentials is concerned, and would also release to the essential industries of the country or to actual war service the men who drive these cars and the mechanics who keep them in repair. Electric cars are common carriers and have to run, and where an electric line is parallel to jitney service it can furnish all the transportation needed both on Sundays and on other days.—Electric Railway Journal.

Don't allow your Thanksgiving Holiday to interfere with your plans for attending the Goodwin banquet on Tuesday night.

Detailed Description of Recently Installed 45,000 kw. Turbine-Generators

By J. P. Rigsby*

The 45,000 kw. turbo-generator unit recently put into operation in the power station of the Narragansett Electric Light Company at Providence, R.I., is of the now well-known Westinghouse cross-compound, double unit type, consisting of a high and low pressure turbine, each connected through a flexible coupling to its own generator, having a capacity of 23,500 kw., and mounted on separate bedplates supported on foundations lying parallel to each other. The generators are arranged to feed separately or together to the main bus.

This type of turbine is very successfully exemplified by the three 30,000 kw. units installed a few years ago in the 74th Street Station of the Interboro Rapid Transit Company, New York. Steam enters the high pressure turbine through suitable governor-controlled valves, passes through this single flow element, and out through an exhaust on the top, and is conducted by means of a receiver pipe overhead to the middle of the double flow low pressure turbine alongside, where it divides, flowing in opposite directions through low pressure blading, then down through the exhaust chambers into two Westinghouse Leblanc jet condensers of the latest type.

The energy given by the steam at full load is equally divided between the high and low pressure turbines, the generators dividing the load in half; at lower loads a greater proportion is carried by the high pressure element.

The unit was designed to operate with a steam pressure at the throttle of 200 pounds with 100 deg. superheat and a vacuum of 29 inches in the exhaust, while the generators have a capacity of 23,750 kva., 11,000 volts, 3 phase, 60 cycles at 0.95 factor, the high pressure element having a speed of 1,800 r.p.m., and the low pressure 1,200 r.p.m.

There are four bearings to each unit, a flexible pin type coupling being used to connect the turbine and generator.

The high pressure turbine is of the single flow reaction type throughout, of a very simple, rugged construction, designed for efficiency and dependability, all parts coming in contact with high pressure steam being made of cast steel, while the exhaust chamber and other parts not subjected to high temperature stresses are of cast iron.

The pressure in the high pressure cylinder varies from a maximum of about 200 pounds at the inlet to atmospheric pressure in the receiver pipe at full load.

With the reaction type machine, high pressure steam is admitted, of course, direct to the cylinder casing instead of into nozzle chambers, as is the case with an impulse type. This presents the problem of perfecting a horizontal joint on a cylinder of considerable diameter that will be tight, and stay tight, against 200 to 300 pounds steam pressure, or any tendency to open, due to distortions from the high temperature.

The high pressure end, or steel part of the cylinder, is composed of two steel castings, 5 feet 10 inches inside diameter and 1¾ inches thick, while at the joint the thickness gradually increases until it merges into a flange eight inches wide, tapering to the outer edge. The bolts 2¼ inches in diameter are spaced about one-third of the way from the inside edge, and four inches between centers. These bolts, or studs, as they really are, are tapped alternately into upper and lower flanges registering with suitable bosses on the companion flange. This method permits of a closer spacing of bolts, removing less metal, and produces a stronger flange than by any other means. No gasket is used, the joint being scraped to a surface.

The four rings containing the blades are not an integral part of the main cylinder, but are made of separate castings jointed in the middle, resulting in simplicity of construction, freedom from strains, and the absence of those difficulties inherent in a complicated steel casting, besides being a distinct aid in manufacturing as the machine work is not all done on one piece, but can be divided among different machines, and finally assembled when each piece is completed. These rings are clamped in place, again saving expensive work on the main castings.

The high pressure cylinder is supported on three points, as usual, one under the governor, or thrust end, and one on each side of the exhaust, near the center line, thus insuring against distortions, or a possibility of misalignment, due to differential expansions between the turbine and generator supports from unequal temperatures.

The high pressure spindle consists of a hollow steel drum about three feet in diameter, carrying most of the blading, there being two blade rings of larger diameter on the one end, and corresponding dummy rings, or balance pistons, on the other. The spindle ends are pressed into the drum and are secured with tee-headed shrink links, which are held in place by the blade and dummy rings.

The stresses in the spindle parts are quite low, these parts being made from ordinary carbon steel. However, strict care is taken in making the castings in order to insure homogeneity, the precautions necessary to secure this uniformity having been learned by long experience.

There are 24 rows of blades in the high pressure turbine, ranging in size from one inch blades, 4 inches long, to 1¼ inch blades, 9½ inches long. These blades are unusually strong and rugged, and they insure the highest efficiency and durability. The maximum mean blade speed is 470 feet per second.

The steam passes out through an exhaust at the top of the cylinder into a 66-inch receiver pipe leading over to the low pressure turbine. A similar exhaust is provided directly below, which connects through an automatic relief valve to the atmosphere.

A gate valve is placed in the receiver pipe, in case it is necessary to operate either turbine alone, the high pressure turbine running non-condensing, under control of its own governor, or the low pressure turbine, on steam admitted through a 14-inch throttle from the high pressure line, it being connected in step electrically with some other unit in the system.

Flexibility on the Steam Line.

Steam is supplied to the unit through a 24-inch header, every care being taken to provide adequate flexibility to the line. A standard Westinghouse type throttle valve with the regular automatic stop features controls the admission. The throttle valve steam strainer and primary steam chest, which are located adjacent to the bedplate alongside the turbine, are spring-mounted, so as not to impose a dead load on the cylinder.

The low pressure element is of the straight double flow reaction type. The steam entering at the top through the above mentioned receiver pipe, passes around the spindle in an annular chamber of ample proportions, and enters the low pressure blading, there being eight rows in each end, ranging

*Engineer, Westinghouse Electric and Manufacturing Company.

from ¾-inch blades, 6 inches long, to 1¼-inch blades, 18 inches long.

The low pressure cylinder rests on four supports applied near the centre line on each side of the exhaust chambers. It is free to expand axially, sliding on these supports, the turbine being anchored to the inboard generator pedestal. A system of radial and axial stays in the exhaust chamber produces extreme rigidity, minimizing the possibility of distortion, or sympathetic vibrations.

The low pressure spindle is composed of a central drum, rigidly secured to the spindle ends. Upon each of these ends are mounted two discs carrying the low pressure blades, the maximum mean velocity of which is only 515 feet per second, which precludes the necessity of using other than a reasonably good grade of cast steel in the blade rings. However, owing to the double flow feature, ample blade area is provided to make the best use of a high vacuum and still maintain a conservative blade length in the last rows. Phosphor bronze blades are used throughout, except the last three rows in the low pressure, which are forged steel.

The low pressure cylinder is entirely of cast iron, composed of a center section and two end sections, bolted and spigoted together, and all split horizontally. The three upper pieces are handled as one, the vertical joints never being disturbed.

The high pressure steam admission is controlled much the same as on all other Westinghouse machines, by means of a powerful, though sensitive, governor, which operates the plunger of an oil relay attached to a floating cylinder mounted on the side of the first, or primary valve. This cylinder by means of levers, controls the primary, secondary and tertiary admission valves. The primary valve, located on the side, admits steam to the bottom of the high pressure cylinder, while the secondary and tertiary valves, being located on the top, systematically about the center line, admit steam to the second, or third stage, as the case may be. Loads of 30,000 40,000, and 50,000 kw. respectively, can actually be carried on these valves.

The bearings employed on this unit are carefully proportioned to preserve a satisfactory ratio between unit pressure and peripheral speed. They are lined with genuine babbit metal, supported on sperical seats, and provided with positive adjustment in any direction. A liberal supply of oil is distributed through a groove along the top, while the sides of the bearings are eccentrically relieved for a distance of 35 to 40 degrees above, and below the center line. This leaves an arc of 100 to 110 degrees on which the journal actually rests.

Both turbines are equipped with double Kingsbury thrust bearings capable of taking the load in either direction, though when running under load the thrust is toward the generator. Under normal operation they are loaded to about 300 pounds per square inch, but are capable of safely carrying twice as much. The maximum peripheral speed is about 100 feet per second. These bearings are not only immersed in oil, but they are supplied with a circulation of fresh oil through passages which deliver it near the centre.

The shafts are sealed with the usual well-known water gland with the addition of an annular steam chamber for the admission of steam so that vacuum can be established before starting up. Water is turned on when the turbine approaches full speed and the steam is turned off. One feature of these glands is that they can be removed for inspection without lifting the cylinder cover.

Each turbine is provided with an oil pump sufficient for its own needs, though both feed into the same oiling system. They are double plunger pumps, running at 165 strokes a minute, with a common suction, but separate discharge.

The high pressure oil necessary to operate the steam inlet valves is taken from one side of the pump on the high pressure turbine, pressure being maintained by a spring loaded relief valve. The total amount of oil used is aproximately 175 gallons a minute. The bearing oil pressure is from five to eight pounds.

This unit, although it does not consist of two separate elements, is started the same as any other machine. Field excitation is supplied to the generators, the throttle on the high-pressure element is opened, and slowly brought up to speed, the low pressure generator operating as a motor, and coming to speed in step with the other. The two machines as a unit can then be synchronized, and placed on the line, remaining in step, and properly dividing their load.

Largest Condenser in the World.

The condenser equipment for the above turbine consists of the largest condensing apparatus in the world. The condenser unit is composed of two separate and distinct low level jet condensers, which can be operated together, or separately, if necessary. If the temperature of the injection water is low enough to warrant it, the operation of only one condenser is necessary to maintain a workable vacuum.

These condensers are connected to form a single condensing apparatus by means of an exhaust connection, ample

Sign Peace at Potsdam

The war will change very suddenly from the appearance of a close-drawn struggle to an absolute German surrender. . . There are three absolutely essential conditions to a satisfactory peace.

The first is that Germany shall be invaded. Too long has she been led to suppose that she is inviolate. This delusion must be shattered.

The second is the occupation of Berlin and the signing of peace at Potsdam, in the very hall in which the plot was hatched.

The third and most important of all is that Germany must pay to the last penny the expenses her outrageous conduct has cost the allies.

This is both policy and justice. She can prepare no other war while she has such a debt, and she will need no army or navy. In 1915 she planned to exact four thousand millions from France alone.

Revolution could only bring the Social Democrats to the top. These people have, with a small minority, in the main sustained the German attack upon her neighbors. We owe them no consideration. Whoever rules Germany inherits the fruits of her criminal conspiracy against the world.

—Sir Conan Doyle.

to allow to permit operating either condenser alone, when necessary.

The same water level is maintained in each condenser by the use of a water equalizing connection between one pump body and the other. This is an absolutely necessary feature and it is provided in order to maintain a constant submergence over the center line of each pump, to provide sufficient head to force water into the runner under vacuum. This water equalizing connection is so constructed that no surges occur between the condensers, it being made in the form of a tee, the bottom of which forms a reservoir. A baffle running almost to the bottom prevents surging.

An air equalizing connection is provided to maintain the same air pressure in each condenser. If both are in operation, the valve may be either open or closed, but it has been found by trial that if one condenser, only, is in operation, the valve must be open in order to have the same air pressure in each.

The condensers are equipped with geared turbine driven pumps running at 500 r.m.p. instead of 700 r.m.p., which latter is standard. This was found necessary, owing to the limited headroom in the basement. These pumps are able to operate with a submergence of 50 inches above the center line of the pump shaft, while 72 inches is necessary with a 700 r.p.m. pump. This resulted in a saving in headroom of 22 inches.

Considering capacity, this unit requires less floor space than any other condenser unit now in operation.

In starting up this condenser it is necessary to use a priming pump. The main turbine is operated non-condensing, or with a slight vacuum, until sufficient vacuum is obtained for the condenser to lift its own water.

The operating company has found it convenient in winter time, when the temperature of the injection water is very low, to operate only one condenser of the twin outfit, and still maintain the vacuum desired, thereby cutting the cost of operation in half. In cutting the condensers out, it is only necessary to close the discharge and injection valves to the condenser not in operation and to operate the other independently.

As a matter of interest, it may be well to note that the above concern uses nothing but jet condensers. Its experience has been that while the boiler feed water is expensive, nevertheless, surface condensers do not stand up under the extremely bad water conditions existing at Providence, and it is necessary to employ jet condensers.

The twin condensers used with the above 45,000 kw. turbine require 18,000,000 pounds of condensing water per hour, 9,000,000 pounds in each condenser. In addition to this 15% more is required for the operation of the air pump.

New York Subway Extension

The New York subway extension system represents the world's greatest achievement in electric railway construction. It consists of 619 miles of track, serves four of the five boroughs of the city and has a capacity of three billion passengers per annum. New York, after five years of construction work and the expenditure of $400,000,000, has completed and put into operation the greater part of her new system of radid transit, known as the Dual System, because the Interborough Rapid Transit Co. and the Brooklyn Rapid Transit Co. have co-operated with the city in developing it.

Four parallel elevated lines and a subway constituted the former rapid transit system in Manhattan. The subway started in Brooklyn, ran north through the eastern part of Manhattan as far as 42nd street, west on 42nd street to Broadway, and then north through the western part of the city, thus forming the so-called "Z." In the new system the eastern part of the old subway has been continued south, thus forming two parallel and independent subways with a shuttle connection under 42nd street. This arrangement is known as the "H." The eastern branch uses the old Brooklyn tunnel, while the western will later on enter Brooklyn through a new tunnel. These two subways are operated by the Interborough Rapid Transit Company. A third subway is operated by the New York Municipal Corporation formed by the Brooklyn Rapid Transit Co. This subway was built between two Interborough subways, which will eventually start in Brooklyn, pass under Broadway, Manhattan, and run over the Queensborough Bridge, at 59th Street, into Queens. In addition, a fourth subway, operated by the Interborough, connects with the old subway at Grand Central Station, and runs through the Steinway tunnel to Long Island City and from thence into Queens. By the extensions vast areas have now for the first time rapid transit and easily accessible to the heart of the city.

Thus the railway mileage of New York has been more than doubled, and it has the most extensive subway system in the world, comprising as it does more than two hundred miles of under-ground railway. Some of the subway routes which honeycombed the soil of the great metropolis has necessitated the boring of tubes under the East river, at an enoromus cost, and under difficulties which would seem to require almost superhuman endeavor.

Nor is the whole story of the efforts to solve the traffic congestion problem of New York been told. Third tracks have been added to the elevated railways on which express service is provided during the rush hours, while instead of one subway there are now three with express service all day. Hence it is no exaggeration to say that the transportation facilities have been increased five fold in down-town Manhattan and three fold elsewhere.

It is hoped that congestion will now be relieved at least for a few years. But no growing city can ever solve the congestion problem, for when new facilities are provided the

(Continued on page 38.)

Canada's Plain Duty

Canada is calling on her people to over-subscribe the Victory Loan of 1918 as an imperative duty that cannot and must not be shirked. The reasons are plain to every business man.

Great Britain, having borne tremendous burdens, naturally finds it difficult to finance her war purchases in this country. The United States is perfecting a vast war machine and her financial resources are required for that purpose. It is necessary, therefore, that Canada should raise within her borders the funds required, not only to carry on our normal and war activities, but also to advance substantial sums to Great Britain if we expect her to continue her purchases here.

Canadians have not been asked to subscribe a war loan since November, 1917, nearly a year. This is an advantage in every way. The long respite has enabled the 1917 Victory Loan to be splendidly absorbed and distributed, and allowed business to proceed without the temporary halt which war loan issues always bring.

The maintenance of the market price of the 1917 Victory Loan at the issue price and even higher, shows the gilt edged nature of the security and furnishes a record in war finance. Their purchase is a duty; a duty that ensures profit.

BUY VICTORY BONDS.

One-Man Car Possibilities for Economy

A special issue of the Electric Railway Journal is given over largely to a discussion of the "economy" side of electric railway operation and in this connection considerable space is given to the one-man or safety car. In a number of cities, both in Canada and the United States, critical situations have been saved by the adoption of this type of car which is alike economical of men, power and maintenance. So far as Canada is concerned it seems to be chiefly the opposition of the operators themselves that has prevented the more general use of this type of car—the chief objection being that men will be thrown out of employment. In these days of labor shortage this does not appeal to us as an argument against nearly so much as in favor of safety cars.

Among other interesting articles in the issue mentioned is one by Mr. John A. Beeler, consulting engineer of New York, in which he makes an analysis of one-man car possibilities.

Of available operating economies the modern lightweight one-man car with automatic equipment is most important in the extent of its applications, in the largeness of its savings and above all in the fact that it increases travel.

By "extent of its applications" is meant all the service in practically all communities of 75,000 or less; a large part of the service in cities of the middle size, and service on such lines of metropolitan cities as are not routed over the more congested streets.

By "largeness of its savings" is meant the reduction in power and platform expense aside from economies in track and car upkeep.

"By "the fact that it increases travel" is meant the stimulation of traffic through increased service, which has had the twofold effect of eliminating automobile competition and of encouraging short as well as long rides.

In a City Below 100,000.

Let us consider the modern one-man car as applied to a specific case, say a city of less than 100,000. The community is served by 25 miles of single track. It should be a splendid electric railway town because of hills which are responsible for grades up to 10 per cent. Slow schedules, bad track, poor cars and two-man crews, however, have made the cost of operation equal 90 per cent of the gross revenues. That the town itself is prospering is indicated by the fact that the car-mile earnings rose from 20 cents in 1911 to 22.5 cents in 1916, with a further rise to 24.5 cents in 1917. Yet the small passenger earnings of $1.66 per car-hour (due largely to slow schedules) and average annual earnings of but $5 per capita indicate that the riding possibilities of this city are far from exhausted.

The reasons why the maximum riding possibilities have not been attained might be classified as follows:

1. Unsatisfactory routing and headways.
2. Low speeds.
3. Unattractive cars.
4. Financial impossibility of increasing service, in view of the low number of miles per man and car, excessive energy consumption and high maintenance.

Re-routing Offers Big Savings in Time.

Ordinarily the first thought in connection with improving service is to shorten the headways; the second is to raise the schedule speed, and the third (if considered at all) is to improve the routing. Yet in the present case re-routing was the most important factor.

Analysis showed that lines Nos. 1, 2 and 3 were satisfactory as to routing, since they brought the passenger directly to the business centre. Line No. 4 not only passed at some distance from the centre, but was also at the bottom of a steep hill. It is true that a transfer to the centre was obtainable, but transfers are an inconvenience at best. This circumstance, plus a ten-minute headway, doubtless tempted persons who lived a mile or two along this line from the business centre to walk instead of ride.

The remaining three lines, Nos. 5, 6 and 7, did not reach the business centre directly, but relied on transfers. The headways on these lines varied from ten to twenty-five minutes. Since the one-way trip length of line No. 5 was 2 miles and of Line No. 7 only 1¼ miles, it is obvious that people in their vicinity could not save much time by riding. As far as crosstown riding was concerned, three and even four transfers might be necessary to ride an equal number of miles!

Hence the basic recommendation was to route all of the lines via the centre of the city so that riding would be encouraged by minimizing walking and transfers. To put the matter in another way: Five minutes saved a person in waiting for a connection or in walking from an offside line is in effect almost as good as cutting a ten-minute headway to a five-minute headway.

As this re-routing was considered in connection with one-man car operation, it is proper to mention that the concentration of all lines in the business section would be well below the saturation point for this character of operation. The averaged combined headway would still be only two minutes, compared with less than one minute in cities where such cars are now in use.

The railway was found to be using summer and winter sets of rolling stock. The open cars were of ten-bench capacity, while the closed cars were of one-man car size, as they seated only thirty to thirty-two passengers each. Because of the duplication and age of the equipment only 40 per cent of the rolling stock, including trippers, was in use on any one day.

Energy consumption was high, ranging from 2.5 kw. hr. per car-mile in summer to 3.75 kw.-hr. per car-mile in winter for cars averaging 25,000 lb. loaded. Thus while the cars were not so heavy as the over-sized cars of other properties, their age and antiquated design were figured as responsible for 200 watt-hours rather than the 125 watt-hours per ton-mile possible with modern, faster one-man cars over the grades of this city. Yet the old schedule speed averaged only 7.5 m.p.h. or little more than twice walking speed. The cost of car maintenance was 2.5 cents per mile.

To supersede this service the one-man safety car, which has since become increasingly popular, was recommended. Under the conditions then obtaining this would have reduced platform expense from 35 per cent to 18 per cent of passenger receipts after allowing a 3 cent differential in wages—an annual saving of nearly $50,000. It would also have reduced energy consumption (the use of thermostats and coasting recorders being assumed) from 15 per cent to 8 per cent of passenger receipts by cutting the cost per car-mile in half—an annual saving of $20,000.

Other possibilities of the one-man safety car in promoting economy and increasing travel will be noted in the following anaylsis of several re-routings:

In the case of two lines the present direct routing and the ten-minute headway were to be unchanged, but the round-trip running time was to be reduced from forty minutes to thirty-five minutes, so that seven cars would do the

work of eight. In light hours the round trip could be made in thirty minutes, with six cars instead of eight, or six men in place of sixteen.

A third line was to be lengthened from 4 miles to 6.5 miles, round trip, by being extended to the business centre. Theoretically the headway was to be ten minutes as before, but actually the overlapping of another line (also on a ten-minute headway) would give the downtown part of the line a five-minute service, thus helping to draw the pedestrian off the sidewalk. The new schedule speed on his line would be 10 m.p.h. instead of 8 m.p.h.

The remaining lines were recommended to be so combined for through operation that on part of the route a twenty-minute headway per line would give a combination headway of ten minutes, while overlapping further downtown would give a two and five-tenths minute service that only a miser could withstand.

To go into further descriptions of the re-routings would lead to needless complexity. In general it was apparent that on the basis of lower operating costs alone it would pay to change over to one-man safety-car operation over the re-routed tracks without making any allowance for those increases in travel and popularity that have been noted in so many communities.

Bell Telephone Changes

Changes in the Bell Telephone Co.'s organization, effective October 1st, are announced. The Eastern Division, which hitherto has comprised Quebec on the East, to Gananoque on the West, has been extended westward to take in Belleville, Kingston, Napanee, Picton, Tweed and contiguous territory. Over this division Mr. R. F. Jones will continue to preside as Division Manager, and his division superintendents will be Messrs. R. Neilson and F. G. Webber, of Montreal, and J. E. Macpherson, of Ottawa. Mr. L. Belcourt, formerly district superintendent at Quebec, becomes manager at Quebec city, and Mr. W. J. Cairns, whose headquarters were until recently were at Brockville, becomes manager at Ottawa.

In the Western Division, extending from Trenton westward to Windsor and Sault Ste. Marie, Mr. K. J. Dunstan of Toronto will continue as Division Manager, assisted by Mr. A. T. Smith, Toronto, as Division Superintendent, and Messrs. R. Burrows, F. Kennedy, R. Hamilton (Hamilton), and J. L. Richmond (London) as District Superintendents

Important changes in the organization of the plant department also go into effect October 1st. Mr. O. E. Stanton of Toronto becomes Eastern Division Plant Superintendent, with headquarters at Montreal, while Mr. J. H. Martin, of Hamilton, becomes Western Division Plant Superintendent.

In the Traffic Department of the Company, Mr. J. N. Groleau is appointed Eastern Division Traffic Superintendent, and Mr. A. G. Watson, Traffic Superintendent of the Western Division.

Norwegian Government Adopts Electric Trucks

By A. Jackson Marshall

After careful investigation the Norwegian Government have placed initial orders with American manufacturers for fifty heavy electric trucks to be used in various communities for the distribution of food, which, in Norway, as elsewhere, is none too plentiful these days, and which must not only be economically used, but must be also scientifically distributed to avoid waste and spoilage, and to assure minimum transportation costs.

Norway, in common with many other European countries, is faced with a gasoline famine, the fluid, when procurable, costing about $1.00 per gallon. Here the horse, as elsewhere, has ceased to be an economic asset, at least in ordinary commercial applications. It is estimated that to feed a horse with grain for one year requires five acres of land, sufficient to support about eight persons. When in addition to such extravagant use of productive land, horse feed must be freighted vast distances across land and sea, using ship tonnage which is other wise urgently required, the horse must necessarily be relegated to the "non-useful occupation" class.

The electric vehicle is the solution to these problems. Water powers are plentiful in Norway, and, as a result, current, for electric vehicle charging, is available in large quantities at small cost. The electric vehicle successfully competed with the "gas" car when gasoline cost fifteen cents a gallon, and current five and more, cents per kilowatt hour. The superiority of the "electric" in Norway is evident. Besides, the electric vehicle possesses the advantages of not requiring skilled mechanical operators,—its simple control enabling it to be successfully operated by older men and women, not required or suitable for direct war duties, and who, as a class, work for minimum wages. Also the "electric" is very seldom out of repair, and consequently does not require that degree of mechanical supervision and repair necessary to keep gasoline trucks in service. Many Norwegian cities have adopted electric vehicles, large orders being placed with U. S. manufacturers. Electric trucks are also being successfully operated by a number of commercial concerns; and demands for electric passenger cars are said to be in excess of shipping facilities.

Personals

Mr. W. J. Cairns, former district superintendent of the Bell Telephone Company, Ottawa, Ont., has been appointed local manager, succeeding Mr. J. E. MacPherson.

Mr. R. A. Sara has resigned as Sales Manager of the City of Winnipeg Light and Power Department, to accept a position with the American Cellulose and Chemical Manufacturing Company of New York.

Mr. J. E. MacPherson, former local manager of the Bell Telephone Company at Ottawa, Ont., has been appointed general superintendent of the company's lines and exchanges in Ottawa district.

Mr. R. V. Slavin has been appointed to succeed Mr. R. A. Sara as Sales Manager of the City of Winnipeg Light and Power Department. Mr. Slavin is a graduate of McGill University, 1910, and has been connected with Winnipeg's municipal plant since the designing and construction days.

Mr. Tetsutaro Morishima, of Tokyo, Japan, electrical engineer to the Japanese Imperial Government Railways, is at present making a tour through Canada and visiting a number of the more important power plants, with a view to obtaining information regarding the power development work in this country.

Mr. E. N. Hyde has resigned his position as general supplies sales manager of the Northern Electric Co., Montreal, and is returning to Philadelphia. Mr. Hyde has made many friends in Canada, where he has long been recognized as one of the foremost exponents of correct lighting. Both by his writings and letters he has done splendid work in advancing the standard of electrical illumination.

Turkey is scarce. Why not postpone your Thanksgiving dinner until Tuesday night and join the Goodwin banqueters at the King Edward at 6.30?

The Dealer and Contractor

Second Annual Meeting of British Columbia Association of Electrical Contractors and Dealers Held in Victoria a Great Success

On September 13 and 14 the British Columbia Association of Electrical Contractors and Dealers held a very successful annual meeting at Victoria, B.C. The Vancouver members and their friends left by the morning boat for Victoria and were met at the C. P. R. wharf by the Victoria members and the visiting delegates from Portland and Seattle. Headquarters were at the Empress Hotel, from whence a trip by motors was taken to the Observatory. On arrival at the Observatory they were introduced to Dr. Plaskett, who gave them a very interesting account of the greatest telescope in the world and its workings, explaining in detail and by movement of the great tube and its parts, the extent and purpose of the work.

From the Observatory the party motored to the Brentwood Plant of the B.C.E.R. Company, inspecting it under the guidance of Mr. Halls, the sales manager. An excellent supper was then in order at the Brentwood Hotel. The toastmaster, Mr. E. C. Hayward, of Victoria, carried out his duties in his usual efficient way. Mr. Halls gave the visitors to Vancouver Island an address of welcome. He explained that Mr. Goward, local manager of the company, had been called away to Vancouver on business, much to the latter's regret. Songs and choruses were then indulged in, closing with the National Anthems of the Allies. The B.C.E. Railway Company kindly provided a special car for the return to Victoria.

Next morning saw a large gathering assembled in the Empress Hotel for the business meeting. The election of officers resulted as follows: E. Bretell, Vancouver, president; C. Moulton, New Westminster, first vice-president; W. Richardson, Vancouver, second vice-president; P. F. Letts, Vancouver, third vice-president; E. C. Hayward, Victoria, vice-president for Victoria Chapter.

As a recognition of the excellent work performed by the retiring president, Mr. C, H. E. Williams, during his more than two years of office, he received the grateful thanks of the Association and was appointed ex-officio member of the executive committee for the ensuing year. Mr. James Angus, retiring from business in Vancouver and moving to California, was granted permission to resign his membership, receiving the cordial thanks of the members for the excellent services he had rendered as a member. In replying he stated that he would perform "missionary" work in California, with the purpose of inducing electrical men everywhere to join similar associations. In order to assist him in the good work he was elected an honorary life member of the Association.

Then followed a lengthy and earnest discussion on affiliation with the National Association, in which the visiting delegates took part. The result was that affiliation was decided on, to date from the 1st of October, 1918.

This meeting was followed by a luncheon at which the speaker of the day, Mr. R. F. Hayward, general manager, Western Power Company of Canada, gave a very forceful and interesting address, in which he spoke of the progress and possibilities of electricity, its great developments during the war and the greater expected developments after the war. He emphasized the necessity of following the great example of Marshal Foch who set himself an "objective," or goal, to secure. An enjoyable launch trip up the Gorge, with refreshments at the Japanese Tea Gardens, terminated a very successful gathering.

The B.C.E. Railway Company paid a very graceful compliment to the electrical visitors in causing the stately Parliament Buildings to be electrically illuminated both nights.

The visiting delegates, Messrs. Jaggers and Sroufe, from Portland, and NePage, Van Riper, Cooley, and Worth, from Seattle, in addition to being of great social value, were of great help to the Association in clearing up many points in connection with affiliation with the National Association.

Specially gratifying features of the attendance were the large representation from the wholesale houses, every firm being well represented; the goodly number of electrical inspectors and the presence of electrical visitors from distant cities, such as Mr. Fulton from Montreal, and Mr. Rowe from Penticton.

At the conclusion of the business meeting, wires were despatched, announcing the affiliation with the National Association, to the Chairman of the National Association and to Messrs. Kenneth A. McIntyre, president of the Toronto Association, and Mr. Wm. L. Goodwin, originator of the Goodwin plan.

How You Should Keep Stock on the Move

By R. F. Behan*

In order to conduct a profitable business sucessfully it is necessary to learn how long different kinds of articles are kept in stock before they are sold. This knowledge is important both from the standpoint of learning how much of the overhead, such as taxes, rent, insurance and other fixed items should be charged against articles carried in stock, as well as to know how often the capital invested in an article is turned over and how often a profit is taken. From this we can learn the percentage profit earned in a year on the capital represented in an article.

All business is done at some rate per month or per year, varying somewhat according to conditions. A careful study of the time that articles are held in stock will have the effect of reducing the amount of stock to the minimum necessary to take care of the business successfully; whereas lack of such study will result in carrying too big a stock with out-of-date articles and considerable deterioration, as well as an undue overhead charge to take care of this slow stock. A dealer of course should always take into consideration in ordering his stock the question of delayed delivery and the distance of the source of supply, the greater the distance

* In Contact

the greater the handicap in this respect and, of necessity, the larger the stock supplied.

Assume for example that you sell $100.00 worth of heating appliances which cost you $70.00, your gross profits would then be $30.00, or approximately 30 per cent of the gross sale. If you can increase your rate of doing business so that you can sell this quantity of stock in one-half the time the rate of gross profits is thereby doubled, whereas the fixed charges or overhead has not increased.

As a prominent sales manager has aptly put it, the answer to the whole problem is: Assuming that your present volume carries sufficient profit to at least let you break even, then any thing you can do to take on business at even lower gross profit, which does not increase your expense, is velvet to the extent of the amount of the gross profit.

If a man invests $20,000.00 and earns 20 per cent gross on his capital on one turnover per year his gross sales would be $24,000.00 per year. If his turn over was on the basis of six months, with the same investment, he would do $48,000 business and the profit would be $8,000 or 40 per cent gross on the investment. If his turnover was on the basis of three months he would do $96,000 business, and the profit would be $6,000 or 80 per cent gross on the investment. If his turnover was on the basis of two months, he would do $144,000 of business, and the profit would be 120 per cent gross on the investment.

From the above it will be seen that it is an exceedingly desirable thing for the manager of a business to constantly watch the condition of his stock and to study the demands and requirements of his customers so that he will at all times be in a position to take care of these requirements, either out of his own stock or out of the stock of the manufacturers or jobbers available, and at the same time not penalize himself with a slow-moving stock which not only bears heavily upon the overhead, but also is subject to depreciation and style charges.

The Modern Need is "Everyday Arithmetic"

Mr. Stanley A. Dennis, writing in Electrical Merchandising, complains of the old fashioned methods of teaching arithmetic which are still extant in this year of modern times —1918. He points out that the type of problem a boy gets in school is about as much use to him when he enters business as his Greek and Latin. He also offers a few common-sense suggestions along the following lines:

Yes, sir! Just think of it! Your tangle-haired youngster playing with his blocks on the floor may know more about business arithmetic at fourteen than you did at twenty-five. As a business man, the chip of the old block has a good chance to outclass the old block himself. Why? Because the folks who write arithmetics are waking up at last. They have discovered that for years they forgot a most important subject. And that is—overhead, or the cost of doing business.

Remember how in your barefoot days you longed to streak it for the old swimming hole, but were forced to stick to your desk and "figger out" this sort of stuff?

If Mr. Martin Culbertson, a retail merchant of Hopkins Corners, buys a barrel of salt at $5 and sells it at $7.50, what was his profit? What was his rate of profit?

If Mr. Silas Whipple buys $10,000 worth of merchandise a year and sells it at 9 per cent. more than he paid for it, what was his profit?

Looks familiar doesn't it? But where do you see anything about overhead in this kind of a problem? And what other definition could a barelegged lad like you infer than that profit is what is left of the selling price after the purchase price of the article is deducted? Yet that is exactly the definition of profit on which many of your school-day playmates are trying to do business to-day, because overhead was the forgotten element in business when you were a slim shaver busy with sponge and slate pencil.

It is a safe bet that the arithmetic you plugged through never mentioned the cost of doing business, and that you started out with only three words in your bookkeeping vocabulary: purchase price, selling price, profit. Then one day you looked helplessly into an empty cash drawer and a new word dropped sizzling into your brain—expense! And as the years have gone by one expense after another has jolted you in turn until at last you've developed a somewhat disgruntled acquaintanceship with a lean and hungry fellow you call "Overhead," to whom you never tip your hat nor offer a cigar.

Well, your boy is luckier than you. He doesn't have to go through that process. Overhead is no longer forgotten, and in his battered "'rithmetic" overhead now has as large a place as the yardstick and the bushel basket. This means that what you have learned under hard knocks about charging in the cost of rent, light, heat, insurance, advertising, freight, and delivery and other items since you went into business for yourself, your boy will learn under gentle instruction from the pages of a down-to-the-minute business arithmetic. So when he opens his own electric shop for the first time some day in the sweet bye-and-bye, he will start his business career set four-square against all the financial hurricanes that may blow against him.

To W. Creighton Peet, chairman of the National Association of Electrical Contractors and Dealers, seems to belong the credit for first discovering an arithmetic which takes care of overhead. Mr. Peet first called the attention of contractor-dealers to this arithmetic in a speech at the recent national convention in Cleveland.

Here is the book: It is "Everyday Arithmetic," published by Houghton Mifflin Company. It is in three sections. Overhead is covered in "Book Three," intended for the seventh and eighth grades.

Here is what this new arithmetic (page 60) has to say about overhead, or expenses, as the book calls it:

A business man has many expenses to meet. A retail merchant, for example, must buy goods to sell; he must pay wages to his clerks and other employees, and he must meet expenses for rent, heat, light, insurance, advertising, freight, and the delivery of goods to his customer. Furthermore, he must see that the money invested in his business yields a fair amount of interest. To make his business profitable, therefore, a merchant must charge enough for his goods, not only to cover their cost, and to pay for the running expenses of his business, but also to leave a balance after all expenses have been paid.

How's that? Good, sound, business horse-sense, now isn't it? And read this problem:

After running a candy store for several months, a young woman found that it took 16⅔% of the amount she received for the candy to pay the clerk hire and other running expenses of the store. At that rate, what did she reckon as the cost of selling a box of candy for which she received 30 cents? For which she received 60 cents?

And this one:

The young woman wanted to find out what kind of candy brought her the highest per cent. of profit. On one grade of

The Goodwin Banquet is timed to start at 6.30 sharp. Don't be late and don't let anything—business or pleasure—keep you away.

chocolate, which she bought for 30 cents a pound she found that she was making a net profit of 10 cents a pound. This was what percent of the cost?

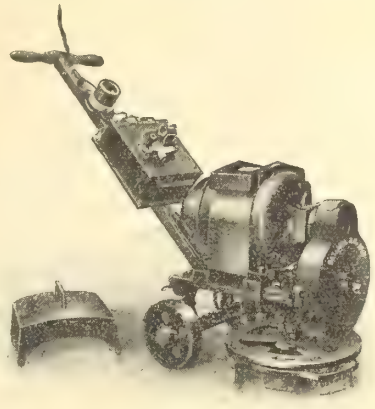
And this one too:

A dry goods merchant buys a suit for $15, and sells it for $25. After taking out the cost of the suit and 20 per cent. of the selling price to pay the running expenses of the store, the dealer makes a profit of how many dollars?

And another:

A merchants' sales for a year came to $42,486; his running expense to $10,206. The cost of his goods at wholesale was $27,052. His net profit was what per cent. of his sales? Of the cost of his goods at wholesale?

Good, are they not? Just for the fun of it, take out your pencil and "work" those four problems. It's good exercise, good practice for your own business.



"It puts things in very clear and definite shape," says Mr. Peet, "and I know that if I had been educated with this arithmetic that it would have been much to my advantage. I think that you will readily agree with me that if all the children should have this one text put into their heads very clearly so that it will remain there, then business will be on a better footing than it is to-day."

Do you know **your** overhead? You can be sure that that boy of yours will know this. Electrical Merchandising has been telling you that if you want to make a 10 per cent. profit and if your overhead is 23 per cent. of your sales you must add 50 per cent. to your cost of labor and materials to get your selling price. But do you **know** your overhead is 23 per cent. or less? Maybe it is more. Can you prove it is less? Can you offer exact figures on some twenty-eight or more items of overhead that can be named? If not, it seems to me I hear your son explaining, about 1930:

"Poor dad. He went under just about the last year of the war. Seems he didn't know just how to handle his overhead. Can't understand it. Must have been something wrong with the arithmetic when dad was a boy."

Electric Floor Surfacing Machine

The Cavicchi Polishing Machinery Co. of Quincy, Mass., have developed a one-man type of motor operated floor surfacing machine for surfacing marble, terrazzo, granolithic, mosaic or any composition stone floors. It is very compact and powerful, and is said to give a perfect finish without

the necessity of hand labor after the machine. This is accomplished by a special flexible wheel; this wheel has individual members, which carry the abrasive; these are so arranged that they move independently of one another, thus following the lay of the floor and producing a uniform finish. The compactness of the machine makes it possible to use it in small rooms and it will finish flush to the wall. The machines are made in two sizes; the larger has a 2 h.p. electric motor, and the smaller a ¾ h.p. The 2 h.p. machine can, it is claimed, do the work of ten men.

The Inquiries Branch of the Department of Trade and Commerce, Ottawa, have received a request from a Sydney importer of electrical supplies for correspondence from Canadian manufacturers, together with catalogues and price lists. The reference number of the enquiry is 636.

Ten Ways to Kill an Association

1. Don't come to the meetings.
2. But if you do come late.
3. If the weather doesn't suit you, don't think of coming.
4. If you do not attend a meeting, find fault with the work of the officers and other members.
5. Never accept an office, as it is easier to criticise than to do things.
6. Nevertheless, get sore if you are not appointed on a committee, but if you are, do not attend the committee meetings.
7. If asked by the chairman to give your opinion regarding some important matter, tell him you have nothing to say. After the meeting tell everyone how things ought to be done.
8. Do nothing more than is absolutely necessary, but when other members roll up their sleeves and willingly, unselfishly use their ability to help matters along, howl that the association is run by a clique.
9. Hold back your dues as long as possible, or don't pay at all.
10. Don't bother about getting new members. "Let George (Kenneth A.) do it!"

Pittsburgh Window Reflectors

James Devonshire, Limited, 701 Yonge Street, Toronto, have been appointed sole distributors for Canada for the Pittsburgh Show Window Reflectors, designed for type C lamps. These are made in three styles—No. 100, shown in Fig. 1, No. 101; and No. 50, shown in Fig. 2. The reflector

Fig. 1

shown in Fig. 1 is suitable for the average window with a height of 8 to 10 feet with depth of one-half to two-thirds of the height, and where the trim extends well up the back wall. No. 101 is designed for the same class of window but gives a little more light at the front, illuminating the back wall at a somewhat lower intensity. No. 50, shown in Fig. 2, is made especially for high, shallow windows or for windows where light is to be cut off at the 50 degree line, such as where there

Fig. 2

is an upper background of glass or where the trim only extends part of the way up. It is also suitable for windows without background or for "island" windows, as the light source is concealed from the opposite side. All three of these reflectors are designed for 100 or 150 watt type C lamps. For larger lamp sizes different holders are supplied.

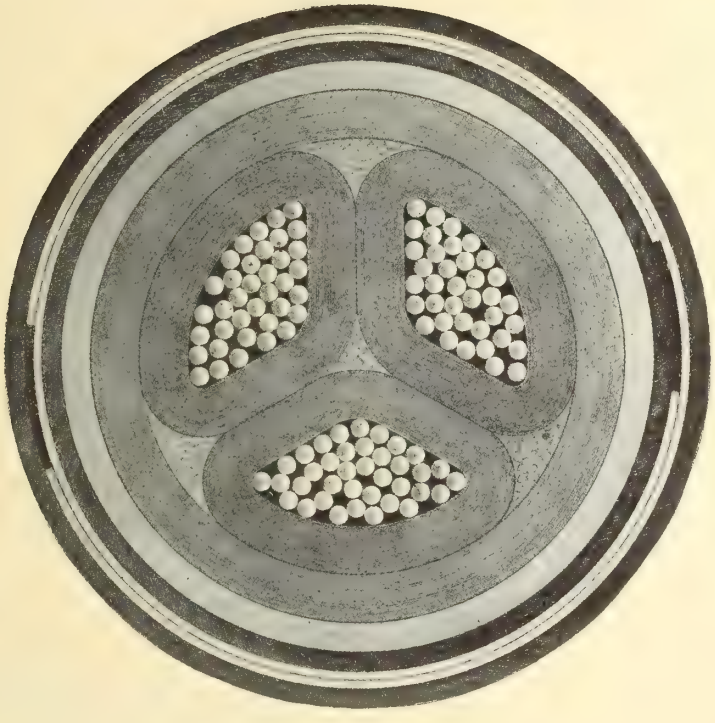
Preserve the fruits of prosperity through a policy of thrift. In the past Canada has been too much a nation of spenders. We should now become a nation of savers. If after this flow of posperity we experience acute depression, it will largely be our own fault. If we save we can weather any storm. What protection shall we have if we fail to save now? What excuse shall we have to offer? The door of opportunity is now thrown wide open to Canadians. Wealth has been showered upon us. Shall we let it all go? If we are thrifty we shall lay aside every surplus dollar. Let us save—for Victory—and for the rainy day that will almost surely follow.

Storage Batteries Ensure Continuous Service

The accompanying illustration shows a typical example of the Northern Electric Titan storage battery installation for working oil switches and emergency lighting in the West Portal sub-station of the Mount Royal Tunnel & Terminal Company, Montreal, at such times as the power might fail. The outfit consists of 64 cells of Titan Sealed in glass jars of a rated capacity of 135 ampere hours. The current requirement for switch operation is a maximum of 75 amperes for a period of from four to eight seconds. The cells, being sealed in, come fully charged and the connections, being bolted, render them easy to install in a minimum amount of time. Batteries of this type are furnished from

stock by this company and this particular set was in and working within a day of the receipt of the order.

The art of storage battery manufacture and merchandising may now be considered as having reached the state wherein the multitudinous demands may be met in the shortest possible time. For emergency work in operating switches, reserve lighting or various breakdown service, the storage battery has a place that careful operators do not overlook. They afford priceless insurance against serious accidents and delays. Interesting data on the application of storage batteries for all types of emergency service, marine lighting, automobile starting and lighting, farm lighting, fire alarm and signal service, telephone service, mine locomotive and all electrical vehicle service may be had by writing the company at Montreal or any of its branches.



The new power transmission line to the Davidson property at Porcupine, Ont., in north-eastern Tisdale Township, is now almost completed.

The Ontario Gazette contains notice that, under the Ontario Companies' Act, letters patent have been issued incorporating "The Ontario Association of Electrical Contractors and Dealers."

The capital stock of the Western Electric Company, Limited, has been increased from $7,500,000 to $10,000,000.

The death occurred recently of Mr. George Black, 71 East Avenue South, Hamilton. Mr. Black, who was a pioneer telegrapher, was born in Montreal, eighty-one years ago, and as a young man entered the service of the G.N.W. Telegraph Company. He moved to Hamilton fifty years ago to manage the company's office in that city, having been previously stationed at St. Hyacinthe and Brockville. He had been manager at Hamilton until ten years ago.

Current News and Notes

Fort William, Ont.

It is stated that the city of Fort William, Ont., will endeavor to secure the consent of the railway board to a seven-cent fare in order to cover the present deficit.

Hamilton, Ont.

The Standard Underground Cable Company of Canada, Hamilton, Ont., have been given a contract for eight hundred thousands pounds of copper wire to be used in the extension of the transmission lines of the West Kootenay Power Company from Grand Forks to Princeton, B.C.

Guelph, Ont.

Continual power shortages and consequent tie-ups on the Guelph street railway have caused the management to issue "delay slips" which will be furnished the passenger upon application to the conductor. These are good for a trip at some other time or the money will be refunded at the railway office.

London, Ont.

On October 7 General Manager Warburton of the London and Lake Erie Railway Company announced that they would cease to operate very shortly and that the work of scrapping the road would commence immediately. A suggestion is now before the city to purchase eight miles of the road that runs between Lambeth and London and connect it with the London Street Railway.

New Westminster, B.C.

Messrs. Fred. J. Hume and C. P. Rumble, of New Westminster, B.C., have formed a partnership and opened a store at 55 Sixth Street to deal in electrical supplies, installations and repairs.

Renfrew, Ont.

A report of the Light Committee of Renfrew, submitted recently, contained a recommendation that the cheap heating rate of one-half cent per kw.h. on small disc heaters be discontinued. The town council, however, will continue the cheap rate on the ground that the 2-cent rate recommended would bar the use of the heaters and that as a measure of fuel economy they should be kept in service as long as there is sufficient water-power to generate current for their use.

Toronto, Ont.

Mayor Church has given notice of the following motion: "That the question of policy re the purchase of the Toronto Electric Light Company, in accordance with the notice of expropriation under the agreement with the city, be submitted to the ratepayers at the coming municipal election.

The Toronto Railway Company has asked permission to increase the fares to a straight 5 cents. The Board of Control, however, unanimously refused any concession. Thus, for the sake of two or three cents a day, every citizen of Toronto must put up with an inadequate service. The mayor and the members of the Board, of course, use their own cars and therefore can generously afford to let the electors suffer.

The earnings of the Toronto Street Railway Company for September, 1918, were $571,636 as compared with $532,007 for the same month in 1917.

Women Sub-Station Operators.

The Edison Electric Illuminating Company of Boston have been very successful in utilizing young women as sub-station operators. At the present time about thirty women are engaged in this work and there is every prospect that the number will be increased. Two sub-stations are being operated entirely by women and the service appears to be quite as reliable as when men were in charge.

The Energy Supply of North America

(Continued from page 24)

small due to their low heads and which cannot be economically developed by the synchronous generator due to the low head and corresponding low speed. The designing character of the induction generator, with regard to slow-speed machines are no better—if anything rather worse—than those of the synchronous generator, and the problem of the economical utilization of the low head water power still requires solution. It is not solved by the induction generator; the latter's characteristic is simplicity of the station, giving the possibility of numerous small automatic generating stations.

New York Subway Extension

(Continued from page 30)

city's growth along the new lines becomes more rapid, which in time results in congestion and demands additional facilities, which, in their turn, cause new growth, and so on around the circle indefinitely.

A large amount of new equipment was naturally needed for the Dual System and for this the Westinghouse Electric and Manufacturing Co. has furnished 600 control equipments and 978 Matroes for the Interborough lines, the total cost of this apparatus being over $3,000,000.

The power requirements are also greatly increased and to supplement its present power equipment, the Interborough Company has installed an 80,000 horse-power Westinghouse turbine generator, which is the largest in the world.

Further extensions are already being planned, notably a tunnel from Brooklyn to Staten Island—but that is in the future.

THE SWEEPERS OF THE SEA

Mr. Punch—"Risky work, isn't it?"

Trawler Skipper—"That's why there's a hundred thousand of us doing it!"

WHITE'S PORCELAIN STRAIN INSULATORS

You want strain insulators that are strong physically, that stand up under the exceptional conditions of the heavy storm; that hold up under a load of sleet; that don't crack when the thunder rolls, the lightning flashes, and the wind whistles.

This is the kind of strains T. C. White Company is making of porcelain in a variety of sizes for different loads, and several designs for varying conditions.

It will pay you to write for bulletin which shows designs and gives the complete data on strain and electrical tests.

Write today.

Electric Vehicles Not Barred on Sundays

In connection with the request of the Fuel Administration that gasoline cars be not run on Sundays, except in cases of necessity, our readers will find interesting the subjoined copy of correspondence reported in the Toledo Times, as having passed between the Milburn Wagon Company of Toledo and the Gasoline Department of the Fuel Administration at Washington:

"C. C. Winningham, Fuel Administrator, Gasoline Department, Washington, D.C.

What is the attitude of the fuel administration in regard to the use of electric automobiles on Sundays? This city has a great many electric automobiles and owners can see nothing in your request to restrict their use. Their use in no way helps in the gasoline conservation, and owners can see no patriotic reason why they should not be used. Electric car owners conserve gasoline 100 per cent on week days as well as Sundays.

Milburn Wagon Company."

Immediately upon receipt of this telegram at Washington the following telegram was returned:

"Milburn Wagon Company, Toledo, O.:

No objection to operation of electric cars on Sundays. Request applies only to gasoline and kerosene propelled automobiles.

Fuel Administrator Winningham."

Rate Increases.

The July Supplement to the Rate Book is the largest supplement thus far issued. Needless to say, in the case of nearly all the changes reported, the rates are increased, and the more general recognition of the necessity for increasing rates for all classes of lightning service, as well as for power, is reflected in the new schedules reported. Many of the increases shown are effected by means of a surcharge, expressed in percentage of the net bills, while many others are effected by a specified increase in the rate per kilowatt-hour consumed.

Two decisions by the California Railroad Commission, granting increases as noted to two companies in that state are of much interest as showing the recognized merit of such claims for increased rates as central station companies are obliged to make at this time. It is expected that the 1919 edition of the Rate Book, which will contain all revisions of rates up to January 1st, will be ready for distribution by the latter part of December.—N. E. L. A. Bulletin.

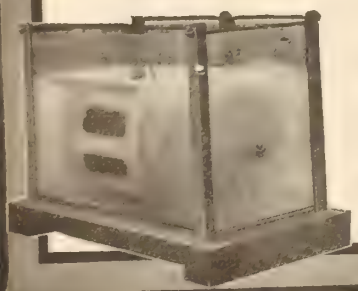
LINCOLN MOTORS

Lincoln Arc Welders

SAVE 50%

You can save 50% — very often more—by doing your boiler plate work with a Lincoln Arc Welder instead of rivetting it.

Lincoln-welded joints are 100% strong — rivetted joints are no stronger than the rivets themselves.



The Lincoln Arc Welder avoids awkward overlapping on corners, thus saving time.

Its heat is greater, more concentrated, and more readily controlled than that of any gas or other welding system, and the current is all usefully employed—there are no "ballast resistances" to waste 50% to 80% of the power taken.

It has been adopted by boiler shops, structural steel works, street car and railroad companies as being the most practical solution of the present labor shortage.

SQUARE D

SWITCHES

Why not a Heart to Heart Talk-

THE ORIGINAL SAFETY SWITCH

with the Plant Electrician?

You know in a general way the many advantages of Square D Switches. Your own experience and observation points out the advisability of eliminating the expensive accidents which result from contact with electrical current by replacing open knife switches with Square D Switches.

But—do you know how easily this can be done—how great a saving it will effect—how inexpensively Square D Switches can be adapted to *your* plant conditions?

Your electrician does. So why not put the Square D proposition up to him? His advice will probably remove the very objections which have made you defer installing Square D Switches.

At least TALK Square D Switches to the electrician—TODAY

GROWTH—

Day after day, week after week, month after month, for the five years that Economy Fuses have been on the market, the sales have maintained a constant growth—not alone in volume, but also in percentage of increase. This is because

ECONOMY Renewable FUSES

are absolutely accurate in operation and cut annual fuse maintenance costs 80%. An inexpensive little "Drop Out" Renewal Link restores a blown Economy Fuse to its original efficiency.

ALLEN FLUX
NON-ACID—FOR SODERING

25 years ago Mr. Allen produced the only non-acid sodering flux ever placed on the market.

Since then Allen fluxes have maintained an easy lead over all competition, being the only Flux approved by the National Board of Fire Underwriters and the preference of America's leading electrical and industrial corporations. Samples Free.

Electrical Books—Special Prices

The following Books are Offered Subject to Previous Sale:

A Handbook on the Steam Engine, by Herman Haeder. Published in 1914 by Crosby, Lockwood & Son. 522 pages, illustrated. Price $3.00.

A Laboratory Manual of Alternating Currents, by John H. Morecroft, E.C. Published in 1912 by Renouf Publishing Company. 248 pages, illustrated. Price $2.00.

Alternating Currents—Examples for Students and Engineers, by Prof. F. E. Austin. Second edition, Vol. I. Published in 1916. 223 pages, illustrated. Price $2.40.

Baudot Printing Telegraph System, by H. W. Pendry. Published in 1913 by Whittaker & Company. 144 pages, illustrated. Price $1.00.

"Central Stations," by Terrell Croft, 1st edition published in 1917, by McGraw-Hill Book Co., Ins. 332 pages, illustrated. Price $2.50.

Direct-Acting Steam Pumps, by Frank F. Nickel. Published in 1915 by McGraw-Hill Book Company. 258 pages, illustrated. Price $3.00.

Direct Current Machinery, Theory and Operation of, by Cyril M. Jansky, B.S., B.A., 1st edition, just published by McGraw-Hill Co., Inc. 285 pages, illustrated. Price $2.50.

Dynamo-Electric Machinery, by Francis B. Crocker, E. M., Ph.D. Published in 1908 by American School of Correspondence. 236 pages, illustrated. Price $1.00.

Electric Arcs, by Clement D. Child, Ph.D. Published in 1913 by D. Van Nostrand Company. 194 pages, illustrated. Price $2.00.

Electric Car Maintenance, by Walter Jackson. Published in 1914 by McGraw-Hill Book Company. 274 pages, illustrated. Price $2.00.

Electric Cooking, Heating and Cleaning, by Maud Lancaster. Published in 1914 by D. Van Nostrand Company. 330 pages, illustrated. Price $1.50.

Electrical Machinery—Principles, Operation and Management, by Terrell Croft. Just published by the McGraw-Hill Book Co. 318 pages, illustrated. Price $2.00.

Electrical Meters, by Cyril M. Jansky, B.S., B.A. Second Edition, just published by McGraw-Hill Book Company. 416 pages, illustrated. Price $3.00.

Electric Railway, by A. Morris Buck, M. E. Published in 1915 by McGraw-Hill Book Company, Inc. 390 pages, illustrated. Price $3.00.

Electric Railway Engineering, by C. Francis Harding, E. E. Second Edition. Published in 1916 by McGraw-Hill Book Company. 416 pages, illustrated. Price $3.00.

"Electric Traction," a treatise on the application of electric power to tramways and railways, by A. T. Dover. Published in 1917 by Whittaker & Co. 661 pages with 518 illustrations and five folding plates. Price $6.00.

Electrical Injuries, by C. A. Lauffer, M.D., published in 1912 by John Wiley & Sons. 77 pages. Price 50 cents.

Electro-Dynamics, by Charles Ashley Carus-Wilson. Published in 1898 by Longmans, Green & Company. 298 pages. Price 50c.

Elementary Principles of Illumination and Artificial Lighting, by Arthur Blok, A.M.I.E.E. Published in 1914 by Scott, Greenwood & Son.. 235 pages, illustrated. Price $1.00.

Elementary Graphic Statics, by John T. Wight. Published in 1913 by Whittaker & Company. 226 pages, illustrated. Price 75c.

Elementary Magnetism and Electricity, by Cyril M. Jansky, B. S. Published in 1914 by McGraw-Hill Book Company. 212 pages, illustrated. Price $1.50.

Engineers' Manual, by Ralph G. Hudson. Just published by John Wiley & Sons. 315 pages, illustrated. Price $2.00.

Examples in Alternating-Currents, (Vol. 1), by F. E. Austin, B.S. Published in 1915. 223 pages, illustrated. Price $2.00.

Examples in "Battery Engineering," by Professor F. E. Austin, E.E. Just published. 90 pages, illustrated. Price $1.25.

Examples in Magnetism for Students of Physics and Engineering, by Prof. F. E. Austin, B. S. Published in 1916. Price $1.00.

First Aid in Case of Electrical Shock, by Dr. John Woodman. Published in 1908 by the New York Edison Company. Illustrated. Price 50 cents.

Handbook of Machine Shop Electricity, by C. E. Clewell. Published in 1916 by McGraw-Hill Book Company. 461 pages, illustrated. Price $3.00.

How to Make High-Pressure Transformers, by Professor F. E. Austin. Second edition, just published. 48 pages, illustrated, price 65c

"Practical Electricity," by Terrell Croft. First edition. Just published by McGraw-Hill Book Co. 646 pages, illustrated. Price $2.50.

Practical Electric Illumination, by Terrell Croft, First edition, published by the McGraw-Hill Book Co. 225 pages, illustrated. Price $2.00.

Principles of Direct Current Machines, by Alexander S. Langsdorf, M. M. E. Published in 1915 by McGraw-Hill Book Company. 404 pages, illustrated. Price $3.00.

Principles of Alternating Current Machinery, by Ralph R. Lawrence. Published in 1916 by McGraw-Hill Book Company. 614 pages, illustrated. Price $4.50.

Principles of Electrical Design—D.C. and A.C. Generators, by Alfred Still. Published in 1916 by McGraw-Hill Book Co. 365 pages, illustrated. Price $3.00.

Radiodynamics—The Wireless Control of Torpedoes and Other Mechanisms, by B. F. Miessner. Published in 1916 by D. Van Nostrand Company. 206 pages, 112 illustrations. Price $2.00.

"Radio Communication, Theory and Methods, with an appendix on Transmission over Wires," by John Mills. First edition, just published by McGraw-Hill Book Co., Inc. 205 pages illustrated. Price $1.75.

Radiation, Light and Illumination, by Steinmetz. Published in 1909 by McGraw-Hill Book Company. 304 pages, illustrated. Price $2.50.

Standard Wiring, 1918 Edition, 24th Year. The National Authority on Wiring and Construction. By H. C. Cushing, Jr. Leather cover, pocket size. Price $1.50 postpaid.

Steam Power Plants—Their Design and Construction, by Henry C. Meyer. Published by McGraw-Hill Book Company in 1903. 158 pages, illustrated. Price 50c.

Steam Turbines, by Robert M. Neilson. Published in 1903 by Longmans, Green & Company. 294 pages, illustrated. Price $1.00.

Steam Turbines, by Kennedy. Published in 1910 by Whittaker & Company. 100 pages, illustrated. Price $1.00.

Telegraph Practice, a Study of Comparative Method, by John Lee, M.A. Just published, by Longmans-Green & Co. 102 pages. Price $1.00.

Telegraphy—A Detailed Exposition of the Telegraph System of the British Post Office, by T. E. Herbert, A.M. Inst. E.E. Third edition. Published in 1916 by Whittaker & Company. 985 pages, 630 illustrations. Price $2.00.

Telegraphy, by Sir W. H. Preece, K.C.B., and Sir J. Sivewright, M.A. Published in 1905 by Longmans, Green & Company. 504 pages. Price $1.00.

Test Methods of Steam Power Plants—A Reference Book for the Use of Power Station Engineers, Superintendents and Chemists, by Edward H. Tenney, B.A. M.E. Published in 1915 by D. Van Nostrand Company. 224 pages, 85 illustrations. Price $2.50.

The Electrical Contractor; Principles of Cost-Keeping and Estimating, by Louis W. Moxey, Jr. Published in 1916 by McGraw-Hill Book Company. 86 pages, illustrated. Price $1.50.

The Dynamo (2 volumes), by Hawkins & Wallis. Published in 1909 by Whittaker & Company. Price $4.00.

The Lighting Art, Its Practice and Possibilities, by M. Luckiesh. First edition, just published by McGraw-Hill Book Co., Inc. 229 pages, illustrated. Price $2.50.

The School of Practical Electricity (Electrician's Course in 2 volumes). Volume 1. Published by Electroforce Publishing Company, Milwaukee, Wis. 410 pages, illustrated. Price $4.50.

The Practical Railway Spiral, by L. C. Jordan, C.E. Published in 1913 by Van Nostrand Company. 155 pages. Price 75c.

Transmission Line Crossings, by Frank F. Fowle. Published in 1909 by D. Van Nostrand Company. 69 pages, illustrated. Price $1.00.

Treatise on Thermodynamics, by Dr. Max Planck. Published in 1903. 272 pages. Price $1.00.

Wray's Manual of Car Lighting. Published in 1915 by Wray Publishing Company. 340 pages, illustrated. Price $1.50.

Electric Power Apparatus, Wires, Cables, Insulators, Transmission Towers and Hardware, Conduits, etc.
41 King Wm. St., HAMILTON, ONT.

ESTABLISHED 1849
BRADSTREET'S
Offices Throughout the Civilized World.
Executive Office:
Nos. 346 and 348 Broadway, New York City, U. S. A.
THE BRADSTREET COMPANY gathers information that reflects the financial condition and the controlling circumstances of every seeker of mercantile credit. Its business may be defined as of the merchants, by the merchants, for the merchants. In procuring, verifying and promulgating information no effort is spared, and no reasonable expense considered too great, that the results may justify its claim as an authority on all matters affecting commercial affairs and mercantile credit. Its offices and connections have been steadily extended, and it furnishes information concerning mercantile persons throughout the civilized world.
Subscriptions are based on the service furnished and are available only by reputable wholesale jobbing and manufacturing concerns, and by responsible and worthy financial, fiduciary and business corporations. Specific terms may be obtained by addressing the company at any of its offices. Correspondence invited.
THE BRADSTREET COMPANY
Offices in Canada: Halifax, N.S.; Hamilton, Ont.; London, Ont.; Montreal, Que.; Ottawa, Ont.; Quebec, Que.; St. John, N.B.; Toronto, Ont.; Vancouver, B.C.; Victoria, B.C.; Winnipeg, Man.; Calgary, Alta.; Edmonton, Alta.

A Lost Opportunity

As a wiring contractor, how many times have you turned down orders to repair the Motors or dynamos of your customers and let them send their work to the maker?

How much have YOU lost in prestige through not being able to take care of your customers' business?

How much have YOU lost in Profit on this business?

Get the habit of handling these repairs. Send them to a **Specialist in Repairs.** Don't send them to the maker. Your customer can do that, and he's already sick of it. The service is too slow. He wants **quick work** and an **absolutely reliable job.** You can give it to him.

Make up your mind **now.** Say "I'm going to get something out of the next repair job in this town."

You have the work of taking out and re-installing the machine **(Profit).** Send us the machine or part with a description of its action or symptom. We'll rush it through for you, give you an A1 job and you come in again on the **Trade Discount (More Profit).**

Others are doing it. Why not you? Write about it.

Every Woman Needs Its Help—Now

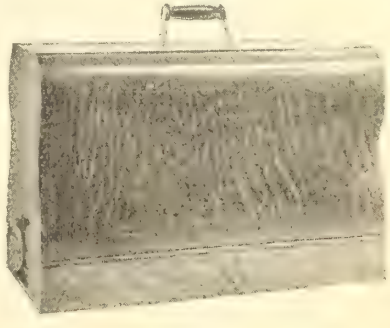
—but when the fall buying season comes, will you be ready?

Why Not Order a Good Supply of

Northern Electric

Portable Sewing Machines NOW?

Remember the greatest need for sewing by electricity is now, when the women of Canada are so extensively engaged in doing their own as well as a large amount of patriotic sewing work at home.



The Northern Electric Sewing Machine eliminates the tiresome, back-aching treadle work of the old method, and enables the operator to do twice as much sewing without effort.

The Northern Electric Sewing Machines are of the highest grade in design and workmanship, and carry a guarantee of complete satisfaction in every way.

Several different types are obtainable in both portable and stand style machines. You can secure either vibrating shuttle or bobbin type.

Closed view of our Portable Type Machines

Two-Wire Metal Molding

Lowest installation cost of any Metal Wiring System

On your next job refer to your Bulletin 101 and place your order with your jobber

Nat has now connected the wires to the Device, secured the Device to the Base—a No. 399-B Keyless Receptacle in this case—and the job is all ready for inspection and a test for grounds. The entire system can be inspected and tested before the capping is placed on and secured with Spring Clips—No. 223.

THE "TYPE S" PORTABLE WHEATSTONE BRIDGE

Useful in the Shop and Laboratory for the Measurement of Resistance. Adapted for Fault Locations in Telegraph and Telephone Lines and Cables.

The Type S Bridge is a thoroughly practical instrument for shop and field use. Being complete in every detail it is ready at all times for immediate use. It is easily portable, its weight being but 8 pounds. The precision of adjustment of its coils (Rheostat 1/10 per cent., Ratio 1/20 per cent.) insures accurate measurements. The galvanometer, the weakest element of such an instrument, is unusually rugged. It is a separate element and may be removed for examination or repair by taking out two screws. The battery is of the ordinary "flash light" type, and renewals may be procured practically everywhere. The price is $66.25 net, f.o.b. Philadelphia, boxed for shipment.

Bulletin No. 530 describes this instrument.

Give It the Pressure Test

Spaulding HARD FIBRE

Put a sheet of Spaulding Hard Fibre under a steam hammer or test it any other way you will for compressing strength. You'll find that its compressing point of 38,000-42,000 lbs. per square inch is in the fibre as well as in the advertising.

A Material of Unlimited Possibilities

Its electro rupture is 200-400 volts per 1/1000 in. of thickness; tensile strength 10,000-20,000 lbs. per square inch; compressing point, 38,000-42,000 lbs. per square inch; shearing strength 9,000-13,000 lbs. per square inch. It can be machined, sawed, stamped, bent, threaded, drilled and finished in many attractive ways, worked up into practically any shape for unlimited purposes.

Made in red, black and grey colors. Send for samples. Our Specialty Department is equipped to machine special parts to your own specification.

Tenders

A few dollars spent in advertising your proposals in

The Contract Record

would result in additional competition, which might save your city or town or your client many hundreds of dollars.

Mr. Manufacturer:

Perhaps not this year, but before many months, peace is almost certain.

It will mean a readjustment of trade.

War orders will cease, and manufacturers will be dependent upon their regular lines.

The manufacturer who has kept his name and his products before his possible customers will be in the strongest position. Good-will cannot be built up in a day.

Now is the time to start an aggressive advertising campaign, to get back the customer you may have unavoidably lost through war contracts.

Let us submit you a proposition to place before the electrical interests of Canada.

The Workman's Time Ticket Tells the Story of R & M Motor Reliability

Where machines are equipped with R & M Motors, their unfailing reliability enables the workman to get maximum production from his machine every hour of every working day. The worker's earnings and the factory output are maintained at top value.

As a result, everyone concerned—mechanic, foreman, superintendent and general manager—all take an interest in the story told on the workman's time ticket and the motors back of the production records.

Where such conditions obtain the man who sold the motors is always a step ahead of his competitors when new equipment is required. As a help in making the sale, he has the good will of everyone in the plant, from the workman at the machine to the general manager.

Central stations, jobbers and dealers find R & M Reliability an asset in their business of constantly increasing value.

Micawber as a Power Controller

The shortage of power which is being felt all over the Province of Ontario is most unfortunate, especially insofar as it interferes with essential industries. The mere curtailment of house, street or store lighting is a comparatively simple matter, which we could all accept gracefully if the exigencies of the war situation demanded it, but it's quite a different matter when munition factories have no power. Unfortunately, with both light and power fed from the same lines, it is impossible to disturb the one without at the same time cutting off the other.

Sir Adam Beck has stated time and again that some of the private companies could develop more power than they are using, and everyone is asking why the Hydro does not buy some of this power, or release some of their load to the companies. If the companies have a surplus of power it is reasonable to suppose they will sell it, and it was generally expected the Power Controller would exercise his prerogative and bring buyer and seller together on an equitable basis. However, this does not appear to be the direction in which he is working—if indeed he is working at all. He, possibly, has inside information telling him that Sir Adam's statements regarding surplus on the private lines is not correct. At any rate the only suggestion that has reached the public to date is that "perhaps" some of the power being exported can be withheld. This sounds unlikely, to say the least, as the U. S. is short of power, like ourselves, and overloaded with munition orders. Rather it looks like an attempt to gain time, and as if the Power Controller, not grasping the actual situation, not vigorous enough to take heroic measures, is hoping, with Micawber, that something will turn up.

It is a great pity the important office of Power Controller, at such a critical time, should be held by a man who, all too apparently, lacks the knowledge and training to enable him to see a solution which is evident enough to others. A lawyer holding an executive engineer's job would be bad enough in peace times, but is inexcusable now, and costing the province and, indirectly, of course, the British Empire, in both money and precious lives.

In the meantime the Power Controller waits for something to turn up.

Buy Victory Bonds

There are three reasonable and, we believe, unanswerable arguments why every Canadian should subscribe to the Victory Loan:

1. Loyalty—You will feel more at peace with yourself if you buy to the very limit of your possibilities, because you will know that you have done what a man ought to do who is proud of being a Canadian and a British Citizen.

2. Investment—Before the war such a gilt-edged investment as this is, yielded about 4 per cent. So it doubtless will be a few years hence. Think what a fortunate position you will be in five years from now to have your money earning 5½ per cent. when current rates for similar securities are about 4 per cent. That will also mean that your bond will be worth, if you want to sell it, considerably more than the par value you paid for it.

3. Prosperity—If we cannot advance money to England at the present moment to pay for the commodities she requires, she will be driven elsewhere to purchase. That would mean no more orders for the things we have to sell. Think what it will mean to the general business situation to have $500,000,000 distributed over Canada during the next few months. Think of the comparative dullness of trade if we don't have it.

Bonds can be bought in denominations of $50, $100, $500, or $1,000. Who is there in Canada to-day that cannot afford one or other of these? Don't hang back because you can't subscribe for a large amount. If every man, woman and child of our 8,000,000 population took the smallest bond of $50, that would mean a total of $400,000,000—more than the minimum asked for.

So whether you subscribe for a $50 bond only, or in thousands, remember—if you have done all you can—that you have squared your conscience, you have accepted a golden opportunity for investment, and you have done your share towards continuing the present lively prosperity of the country.

Public Utility Impertinence

A recent tabulation of the expenses of the average householder earning an income of from $1,000 to $2,000 shows that less than 3 per cent. goes for electric light and street car fares combined—that is from $30 to $60 a year.

This is one of the smallest sums entering into the annual expense account. It is comparable with the item of newspapers alone which, at a cost of 4 cents a day, (morning and evening), with a special on Saturday night, runs into the sum of $15.00. Of course we must not overlook the fact that the price of newspapers has doubled since the war began.

It is about the same as the price of shoes which at two pairs each for a family of four, averaging five dollars,

amounts to $40. (The price of shoes has advanced from 50 to 100 per cent. since 1914.) It is much less than the price of clothes, for which this typical family of four would require at the very least $200.00—an increase of more than 100 per cent., in some cases, since the war.

And what of the other items? Rent increased; every article of food—milk, bread, meat, sugar, vegetables—many of them cost more than double what they did in the old days. It truly is hard for the man of small means to make both ends meet. And the situation is all the more irritating and unbearable because there is evidence that many of the increases are pure profiteering—taking deliberate advantage of the times to raise prices more than increased costs justify. Taken altogether, it probably costs a man who formerly kept his family on $1,000, not less than $1,700 or $1,800 to live in the same way to-day—an increase not at all justified by the actual increased cost of the necessities of life.

In a number of towns and cities in Canada there are two items that have not advanced—electric light and street car fares, the items which, combined, cost the householder from $30 to $60 a year. Yet the cost of operating these utilities has greatly advanced, as can be seen by the average citizen, since this cost includes wages and materials, both of which are much more expensive. Is it any wonder if an electric light or a street railway system should make a request for an increase in the price of its product? Surely common justice demands a recognition of their claims, without argument. Indeed, this recognition has been made in a number of cities in Canada already and the rates and fares have been increased.

Yet, when the railway company in a large Canadian city asked, a few days ago, for an increase in fares, amounting to about 25 per cent., the mayor of that city called it "impertinence."

One cannot but wonder what his vocabulary produces when he pays for his boots, his suits of clothes, his top hats, his groceries, his coal, his meagre mid-day lunches!

But to sum up:

The commodity dealer in groceries, coal, rent, etc., is a free agent—has little at stake, assumes no responsibility, acknowledges no obligation, comes and goes as he likes—yet he squeezes his customers for all the trade will possibly stand, and they accept conditions cheerfully.

The public utility is tied by contract and franchise, has heavy financial obligations, assumes definite essential responsibilities, must work constantly and continuously to fulfill its obligations, is tied hand and foot over long periods of time, is held down at best to small financial returns—yet the public, if the mayor of this large Canadian city is representative, calls them impertinent when they ask a nominal increase for their products.

In a nutshell: The retailer of shoes, clothing, coal, rent, groceries, asks an increase of 100 per cent. which, in many cases, also means 100 per cent. or more profit—and we call it "war," "shortage," or what not. The public utility asks an increase of 25 per cent. which at best might represent a yield on investment of 5 or 6 per cent.—and it is "impertinence."

What do you think of the mayor's judgment?

Winnipeg Listening to Reason

The board of conciliation appointed to investigate matters in dispute between the Winnipeg Electric Railway Company and its motormen and conductors has recommended an increase in wages and in order that this increase may be paid the board has stated that the company should receive higher fares. The report further states: "It appears by the evidence before us that the company has paid no dividend to its shareholders since December, 1915, and at the present time, notwithstanding the elimination of jitney competition, the operating expenses and fixed charges of the railway exceed by several thousand dollars per month the railway's actual earnings. . . . In justice the public should pay an adequate war compensation for a service which cannot be rendered except for war prices." The wage increase recommended is as follows: 39 cents an hour for the first six months; 41 cents for the second six months; 44 cents for the second year, and 47 cents for the third and succeeding years of continuous service. Time and a half for overtime is also granted.

BUY VICTORY BONDS

EVERY squadron commander in the Royal Air Force in France is a Canadian. How many bonds can you take?

Electrical Supply to Military Hospitals

The Department of Public Works have received tenders for the construction of a light and power transmission line at St. Anne de Bellevue, P.Q., for the group of military hospitals recently erected there. Current will be supplied by one of the public utility companies from a point on the main road, near the buildings. The poles will be 30 ft. above ground, with 7 in. tops, and guyed at the turns and ends with standard guy wire and anchors. The cross-arms are to be of the standard 4-pin type, fitted with locust pins, double cross arms being used at the turns and ends. The insulators are of the double petticoat type. The primaries at the pole connecting with the company's lines will be protected by multi-gap lightning arresters. The line wire is to be double-braided.

The pole transformers will consist of seven lighting and four power transformers. The former, ranging from 5 to 50 kv.a., step down, will be single phase, oil-cooled, 60 cycle, with primaries of 2,200 v., and secondaries of 220/110 v., three wire system. The power transformers are of the same type, the primaries being 2,200 v., and the secondaries 550 v., connected in pairs for three-phase, 550 v., distribution. All transformers are to have an efficiency of 98 per cent. at full and half and 97 per cent at 25 per cent load.

Government Has Made Formal Protest

It is announced from Ottawa that the Canadian Government has made a formal protest to Washington against the action of the International Waterways Commission in granting permission to the St. Lawrence Power Company to dam the south channel of the St. Lawrence River at Long Sault, and an Order-in-Council has passed outlining the position of the Canadian Government. Canada takes the stand that under the Ashburton treaty, and the later treaty of 1909, it is definitely stated that navigation in the boundary waters is not to be interfered with. The Government is of the opinion that in view of these treaties the International Commission exceeds its rights in assuming the responsibility of giving authority to proceed with the weir.

The Hamilton Hydro-electric Commission have granted a war bonus of 20 per cent. to all women employees drawing less than $1,000 a year and 20 per cent. to all male employees receiving less than $1,200 per year. The bonus dates from October 1 and is for one year.

The city council of Brantford, Ont., will submit to the electors next January a by-law authorizing a debenture issue to the amount of $100,000 for the purpose of extending the street railway tracks in the Terrace Hill district.

Possible Wartime Lighting Economies

Report of Committee on War Service of the Illuminating Engineering Society Before Recent Convention

Every citizen can assist the Fuel Administration in its efforts to conserve the coal which must be saved if the war ability of the nation is not to be impaired. Principally this may be done by adopting good practice in house heating. To a lesser but important extent it may be done through careful economies in lighting.

This guide to economies in lighting has been prepared by the Committee on War Service of the Illuminating Engineering Society[1] at the request of the Fuel Administration extended through the National Committee on Gas and Electric Service.

It is the patriotic duty of each citizen to see to it that no fuel is wasted in his service. The technical guidance here offered should make it possible for each to adopt lighting practice which will conserve fuel without impairing public welfare or diminishing useful accomplishment.

The following simple rules lead to the elimination of waste in lighting, both by limiting the use of artificial light to the minimum necessary number of hours per day, and by promoting the most efficient use of artificial light during those hours.

Elimination of Waste in Lighting

Do not light lamps when sufficient daylight can be had.

Extinguish lamps when leaving a room unoccupied even for a few minutes. Use pilot flames on gas lamps. They facilitate relighting and leave no excuse for failing to extinguish lamps when their light is not needed.

Do not use lamps which contribute merely to decoration.

Do not use more lamps or larger lamps than necessary.

Do not use all the lamps when part of them will suffice.

Use single large high efficient lamps rather than a number of small lamps.

In halls, bathrooms, etc., turn down gas lamps when full light is not needed. Use electric turn-down lamps or turn-down devices.

Do not use electric lamps of the carbon filament type where the more efficient tungsten filament lamps can be employed.

Do not use open-flame gas burners where the more efficient mantle burner lamps can be employed.

Do not use blackened electric lamps or broken mantles or discolored chimneys. New lamps are more efficient.

Do not use indirect or semi-indirect lighting fixtures in conjunction with dark ceilings which absorb a large part of the light.

Use light colored reflecting surfaces (ceilings, walls, etc.) wherever practicable. These reflect much of the light and make it possible to employ fewer or smaller lamps.

Clean lamps, shades, globes, windows, etc., thoroughly and often. Dirt absorbs light.

Consult the lighting company for advice as to best lighting practice and latest devices.

Use daylight during the war in preference to artificial light wherever and whenever possible.

Raise the shades to let in the daylight instead of lighting lamps.

Arrange window shades to admit maximum daylight when desired. A good arrangement is to have two rollers at the middle of the window, one drawing up and the other down.

Ceilings and upperwalls should be light colored and clean. Light colored surfaces reflect five to ten times as much light as dark surfaces. They conserve both daylight and artificial light.

Refracting or diffusing glass in windows helps to spread the light to distant parts of the room.

Whitened surfaces on building exteriors (especially about courts of high buildings) give more and better daylight in opposite buildings.

Keep windows and skylights clean. Dirty windows may absorb half the daylight.

Dust window screens frequently. Remove them as soon as the insect season is passed. They absorb one-third of the daylight.

Carry out operations requiring strong illumination near windows where plenty of daylight is available.

Arrange machinery, furniture, etc., so that daylight falls on objects to be seen—not on the eyes.

The considerations underlying these rules for economical lighting are as follows:

Fuel Consumed in Artificial Lighting.—The total coal output of the country this year is estimated at 700,000,000 tons. About 2½ per cent. of this is composed in the production of artificial light. Electric lighting requires about 12,000,000 tons. The net consumption of coal in gas lighting is smaller (to which, however, a large amount of oil is to be added).

Relative Efficiencies of Various Lamps.—Most artificial light is produced by consuming fuel. Whenever a lamp is extinguished, the consumption of fuel is diminished. A small lamp consumes less fuel than a large lamp. Inefficient lamps require more fuel for a given production of light than do efficient lamps. The gas mantle lamp will produce five times as much light as the open-flame burner for the same consumption of fuel. An intelligent choice of lamps therefore makes it possible to reduce the consumption of fuel.

Shades and Globes for Lamps.—Modern lamps are so brilliant that they may injure the eyes if used without protective equipment. Shades and globes conceal them from view, soften and diffuse the light, and, where desired, redirect a considerable part of the light in the direction needed. Shades and globes never increase the total quantity of light, but an efficient reflector will usually increase the light where it is needed. With such a reflector a smaller lamp may suffice, thus saving coal. The advice of the lighting company should be sought when selecting such equipment.

Painting.—As a rule, at least one-half, and sometimes practically all, of the light utilized in interiors is received by reflection from walls and ceilings. Good light tinted paint when fresh rarely reflects more than one-half of the light which falls upon it. The proportion of light reflected from good white lead and oil paint under average conditions diminishes by about 10 per cent. a year. The same is true of calcimine and similar coatings. It is apparent therefore that

[1] Underlying the accepted principles of illumination are requirements for safety, conservation of vision, aesthetics, comfort, convenience and economy. The Illuminating Engineering Society is committed to the preservation of these principles and to their application in lighting practice in the public interest. A number of recommendations here presented, particularly those advocating decreased use of light, are calculated to save fuel rather than to bring about most desirable illumination conditions. These are to be regarded solely as a war measure, justifiable in the present emergency, but otherwise not to be approved.

there is an opportunity for improving lighting efficiency through the employment of the best finishes for ceilings and upper walls. Painting white ordinary light tinted surfaces may increase the light reflection by as much as 50 per cent. Therefore in order to save fuel in lighting, wherever it is practicable paint ceilings white; employ light tints for the upper parts of walls; and use paint that is non-porous and easily cleaned.

Extravagant Lighting.—Extravagance in wartime is unpatriotic. It involves application for selfish purposes of money and energy necessary to winning the war. Lighting in excess of that which is necessary, and lighting for needless display of decoration at such a time is extravagant.

Display Lighting.—The question of illuminated advertising display is a part of the larger question of general advertising practically all of which involves consumption of fuel. The desirability of curtailing lighting of this character would appear to depend upon the necessity of reducing advertising in general.

Proper lighting display has a place in maintaining the morale of the people no less important than amusements and recreation. Display lighting also has a certain utility in providing necessary illumination. General and needlessly extensive display and inefficient methods of lighting display under present conditions are extravagant. In planning lighting of this character every economy of energy not inconsistent with reasonable effectiveness of the lighting should be sought.

Fallacies in Lighting Economies.—Removing reflectors or shades from lamps in order to "get more light" defeats the object. The raw light from glaring bare lamps is less effective than a smaller quantity of reasonably diffused light not exposed to the eye.

Attempting to economize by reducing the number of lamps or by using smaller indiscriminately is unwise. In nearly every case ample illumination is essential to useful accomplishment. The most successful conservation is elimination of waste of light, not reduction of use of light.

Where Not to Save Coal.—In wartime human energy and financial resources are to be conserved as well as fuel. Except in the greatest emergency it is unwise to save a little coal at the expense of waste of labor or impairment of health or menace to the safety of the public. Coal saved through the improvement of lighting equipment is clear gain. To diminish lighting standards in industrial plants, offices and other places where accomplishment depends in part upon vision is to reduce accomplishment or output. In such places, therefore, lighting should not be reduced. On the contrary, an increase in the standard of lighting may be the truest economy and in the best interests of the nation. The liberal use of light for protection of important property, munition factories, public works, etc., is likewise in the public interest, and under present circumstances no attempt should be made to save fuel through the reduction of such lighting.

Curtailment a Local Matter.—In an acute local fuel situation an absolute lack of fuel may result in largely curtailed activities. If there is no fuel, industry must cease. Such a critical situation obviously demands radical curtailment of lighting beyond anything which is contemplated for general adoption.

In certain localities in the height of winter there may be a power shortage due to abnormally taxed generating capacity. This likewise may necessitate local lighting restrictions of a more extreme character.

In either event, when such a situation occurs, the problem is a local one, the handling of which must be governed by the particular circumstances.

Specific Applications.—Intelligent application in any lighting installation of the suggestions contained herein will result in appreciable saving of fuel. In some classes of installation certain of these methods of saving have more conspicuous application than others.

Store Lighting.

The amount of fuel consumed in store lighting is of sufficient magnitude to make a consideration of possible economies worth while. Waste is usually due to causes rather easy of correction without involving a decrease in the effectiveness of the illumination.

Economies may be effected by:

1. Eliminating excessive illumination.
2. Avoiding the burning of lamps when not actually needed.
3 Saving the light wasted by dirty glassware, dark walls and ceilings and inefficient equipment.

I. Illumination in stores should be only that necessary to enable customers to see comfortably and plainly even where the closest discrimination is required to the end that they may make selections and judgments quickly and satisfactorily and to enable salespeople to perform their duties quickly and easily. The degree of illumination suitable for any particular case may be determined by actual trial through the use of more or fewer lamps or of lamps of greater or lesser power.

II. Lamps should be so controlled that only those actually needed will be in use at any time. In small stores this may be accomplished by controlling each individual lamp or cluster of lamps at the fixture. In larger stores the lamps farthest removed from the windows should be on separate circuits being switched on first as daylight diminishes, the outer lamps being turned on later as necessary. In all cases the greatest practicable use should be made of daylight.

III. The loss of artificial light due to dirty glasswares and dark or dingy ceilings and side walls ranges from 30 to 50 per cent. and may be avoided by renovation at necessary intervals. Ask your lighting company.

Large lamps are usually more efficient than small lamps and where practicable installation should be altered to consist of the fewest lamps from which uniform illumination may be obtained under the conditions of use. Show windows should be lighted by lamps with efficient reflectors; by the use of these it is often possible to save from 25 to 50 per cent. of the energy required for illumination without impairing the illumination in the window. Under no circumstances should bare lamps be visible from the street as this renders the eye less sensitive and makes a higher intensity necessary in the interior of the store, thus defeating the purposes for which these economies are urged.

Hotel Lighting.

It is suggested that waste in guest rooms be reduced to a minimum by having a notice, probably a card, placed near the door reading:

> U. S. F. A.
> SEAL
> "It is requested by the U. S. Fuel Administration that you kindly turn off the lights when leaving the room, and help save fuel."

All employees of the hotel, especially the housekeepers having charge of the guest rooms, should be cautioned to see that lamps are not left burning when rooms are unoccupied and that when rooms are being cleaned only necessary lights are turned on. Bell boys should be instructed to turn on only the main or overhead lamp when showing the guest his room.

In dining rooms where two systems of lighting are in use, such as overhead and table lighting, one of the two should be reduced or eliminated entirely. Where overhead

lighting is sufficient, table lamps solely for decorative effects should be done away with.

In public rooms such as cafes, lobbies, writing rooms, etc., the illumination should be reduced to a point consistent with comfort. All decorative lamps, around mirrors or on brackets, etc., not absolutely essential to produce illumination of a sufficient intensity to avoid feeling of undue depression or gloom should be eliminated.

While it is important as a measure of safety to keep stairways, passageways, and halls adequately illuminated, it should be remembered that hall lights burn long hours and in cases where convenience or safety is not menaced reductions as to number and size of lamps must be made.

Service rooms where lamps are allowed to burn constantly should receive consideration, for example in large barber shops where only a few chairs are in use lights over the other chairs should be turned off. In the kitchen only those parts of the room actually being used for preparation of food, washing the dishes and the like should be lighted.

Home Lighting.

What can be done in the home to conserve fuel? To answer this question let us ask what things in the home are done by means of fuel. Well, heating, cooking and lighting are mainly done by its use; and either directly or indirectly this fuel is mainly coal. So that to conserve fuel in either of these three uses there are two methods to be considered: (1) To make sure of the efficiency of the appliance used, and (2) To limit the time of its use to a minimum.

It may not be generally known that the percentage of fuel used in the homes of Americans for these three purposes is about as follows:

For heating (house and water) ...	87 per cent.
For cooking...	11 per cent.
For lighting	2 per cent.
	100 per cent.

Our specific purpose here is to consider the conserving of fuel in home lighting.

Home lighting is by means of two kinds of light—Natural or daylight, and Artificial light. To properly use the former is to aid in conserving the latter, which requires coal.

At periods near dawn and near dusk, and during the heavily clouded days we supplement daylight by artificial light; and many times we do this unnecessarily because we do not make maximum use of the daylight at hand.

Daylight. (A) Keep window panes cleaned; as much as half the light may be absorbed by thick films of dust.

(B) Keep insect screens dusted; when repainting use light colored paint instead of dark, and do not paint the mesh closed; or else use galvanized wire which is light in color and durable. Also, remove the screens as soon as the need for them has passed. Many screens stop one-third the light.

(C) Housewives will be reluctant to give up, even to a degree, their use of lace curtains; but some minutes of artificial lighting may each day be saved by a judicious use of these during very bright periods only.

In short, use daylight wherever possible in place of artificial light:

Early to bed and early to rise
Saves our boys, fuel and cargoes and lives.

Artificial Light.—It cannot be said, in general, that our homes are overlighted; but as first stated above, it is true that many of them use light inefficiently, and many of them are lighted overtime. It is desirable, therefore, to correct both of these wastes, and to be watchful against their recurrence. To this end, may we not get this habit: When we look at a lighted lamp let us consider the rays streaming from it as streams of coal made incandescent; and remember **so long as the light flows, the coal flows!**

If it sems difficult to get every member of the family inculcated with the habit of light saving, then much may be accomplished by appointing one of the younger members a Light Monitor, charged with the duty of seeing that no extra or wasteful light is used. He will probably enjoy the duty and responsibility.

Recommendations for improving the efficiency of the lighting will be given in later paragraphs.

Having our equipment efficient, and desiring to further economize in the use of artificial light, let us not so much strive for a less lighted room as for less rooms lighted. Can we not work toward the old idea of the common family lamp, having it modernly equipped and supplying adequate light for all surrounding it?

Recommendations.

1. Turn off all lamps not in use.
   Even if you are coming back in a few minutes, you can turn it on again. Pilot burners or wall switches will be found a great incentive to this practice where lamps are in intermittent use.
2. Clean lamps regularly. (Not merely occasionally.)
   Dirty shades and reflectors may reduce your light one-half. It is proved economy to replace dim electric lamps or broken gas mantles with new ones.
3. Keep lamps properly shaded.
   Lamps having proper reflectors will give best service. Unshaded lamps cause eye-strain. Poorly designed shades waste light. Consult your lighting company.
4. Use only modern lamps.
   Replace open-flame burners with mantle lamps. Replace carbon electric with tungsten lamps.
5. Regulate light for proper requirement.
   Use turn-down lamps for hallways, kitchens, bathrooms, etc., where night lights are required.
6. Avoid the use of lamps for decorative purposes only.
   This is a form of extravagance unsuited to war times.
7. Do not use large size lamps in small size reflectors.
   This results in exposed lamps and glare.
8. Do not use indirect or semi-indirect units with dark ceilings.
   Such ceilings absorb too much light, instead of returning it downward in useful directions.
9. Again—Do not use artificial light where natural light may be used.

Lighting Economies in Offices and School Rooms.

Very large economies in the operation of lighting systems in offices and schools may be effected by observing all of the precautions listed below, and this without reducing the general illumination, which is seldom of an intensity higher than that required for the conservation of vision.

Control of Lamps.—Operate the lighting units for a given area only when such area is in use. They should not be turned on during any part of the day when the natural lighting will suffice. Place the responsibility for such careful operation on designated individuals.

Parts of the room remote from the windows may require artificial lighting when natural light is sufficient near the windows. Connect the switches, if possible, so that the light sources may be turned on in rows parallel with the windows, and the artificial lighting thus used in the several sections only as is necessary.

Often the greatest waste occurs through the lighting of an unnecessarily large number of rooms during the hours of cleaning. Every building superintendent and janitor

should insist that lamps be lighted in a given area only when the cleaners are actively engaged there, and that the minimum number be turned on which will permit the work to be done properly.

Cards or signs should be displayed prominently in the various rooms requesting tenants to turn on only such lamps as are necessary to their work and urging that all lamps be extinguished when daylight will suffice and when the tenant leaves his office.

Reflecting and Diffusing Accessories.—Use bowl-frosted lamps with open reflectors and be sure that the reflectors are deep enough to protect the eye from the glare of the filament or mantle. Larger reflecting fixtures with glass diffusing bowls suspended below the lamps further soften the shadows and reduce the demand for local desk lighting. Indirect and semi-indirect fixtures produce the best conditions for vision in school rooms and offices.

Clusters of lamps under flat shades produce glare and distribute light ineffectively. The larger lamps are the more efficient. Therefore a lower wattage will suffice in a single large lamp with deeper reflecting or diffusing accessory.

Cleaning of Windows.—Windows should be cleaned at frequent intervals to allow the maximum use of daylight and limit the house of artificial lighting.

Painting of Light Wells.—Paint the light wells white. This may reduce the period of artificial lighting by several hours each day, and improve the daylighting at all times.

Removal of Window Screens.—Where windows of offices are screened, the screens should be removed just as soon as the necessity for their use has passed. They absorb a high percentage of the daylight and require artificial lighting to be turned on for considerably longer periods.

Cleaning of Fixtures.—Dust accumulating on school and office fixtures frequently reduces the intensity by 25 to 50 per cent. Clean the units regularly and at short intervals to insure maximum output for the fuel consumed.

Wall and Ceiling Surfaces.—White ceilings and, to a lesser extent, light colored walls add greatly to the efficiency of any office or school lighting system. The added diffusion of light is also particularly valuable here. It is necessary that ceilings, especially should be refinished whenever they become darkened. With indirect or semi-indirect lighting the refinishing of the ceiling and cleaning of the lighting units will frequently increase the intensity 50 to 100 per cent., permitting a reduction in wastage to the next lower size of lamp.

In offices and school rooms the requirements of vision are exacting. The occupants must view fine detail and work in one position for long periods. The light from a lamp therefore enters the eye constantly from one direction and will prove annoying and harmful if too bright. Reflections from polished surfaces and sharp shadows also interfere with vision. If the general illumination is from amply diffused sources of proper wattage, all individual desk lamps may be dispensed with.

Economies in Fuel for Industrial Lighting.

In almost every plant there is waste in the use of light, the elimination of which can be accomplished without retarding production, impairing the vision or menacing the safety of the employees. The principal sources of waste are the following:

Inefficient Lamps.—Replace carbon electric lamps by the modern efficient tungsten filament lamps. Substitute mantle burners for open-flame gas jets. These substitutions will result in a saving of three-fourths of the fuel used for a given candlepower.

Where clusters of lamps are employed under shades replace them by a single larger lamp with a suitable reflector. The larger electric lamps are the more efficient. A lower wattage may be used in a single unit than with a cluster.

Improper Reflecting or Diffusing Equipment.—Flat reflectors allow much of the light to escape to the walls instead of directing it to the work. They also leave the bright light source exposed to view and the glare interferes with vision, causing a demand for still higher intensities. Use reflectors of the dome or bowl shapes for greatest economy. Except where lamps are mounted in high bay areas use bowl-frosted lamps to reduce glare reflected from the work and to soften shadows.

Faulty Location of Units.—Space lamps close enough to give uniform lighting and with reference to the work, so as to avoid bad shadows. This permits the use of a minimum wattage in the general lighting and makes it possible to remove most drop lamps or local lighting. Drop lamps within control of the workmen are frequently burned by him throughout the day when no necessity exists.

Maintenance.—Keep lamps and reflectors free from dust by a regular schedule of cleaning at short intervals. In many factories dirty reflectors absorb half of the light produced by the lamps.

Have windows washed frequently. This will greatly improve the natural lighting and permit the use of daylight alone for more hours per day.

The Kaiser does not want you to Buy Bonds.

Keep ceilings and upper walls well painted in white. When dark or dirty they will absorb so much light that more artificial light must be furnished.

Wasteful Burning of Lamps.—So far as possible do all lighting from a general overhead system out of the control of individual workmen. Make some individual in each department responsible for seeing to it that lamps are lighted only in such areas and for such periods as necessary.

Areas at a distance from windows often require artificial light when natural lighting is sufficient near the windows. Switching arrangements should be such as to make this possible.

Table I.

	Foot-candles at the work	
	Ordinary practice	Minimum
(a) Roadways and yard thoroughfares	0.05- 0.25	0.02
(b) Storage spaces	0.50- 1.00	0.25
(c) Stairways, passages, aisles	0.75- 2.00	0.25
(d) Rough manufacturing, such as rough machining, rough assembling, rough bench work	2.00- 4.00	1.25
(e) Rough manufacturing, involving closer discrimination of detail	3.00- 6.00	2.00
(f) Fine manufacturing such as fine lathe work, pattern and tool making, light colored textiles	4.00- 8.00	3.00
(g) Special cases of fine work such as watch making, engraving, drafting, dark colored textiles	10.00-15.00	5.00
(h) Office work such as accounting, typewriting, etc.	4.00- 8.00	3.00

Note.—Measurements of illumination are to be made at the work with a properly standardized portable photometer.

Change of Address

The address of the Hessco Electric Manufacturing Company has been changed from 210 Adelaide Street West to 33 Church Street, Toronto.

Canadians Hear About the Goodwin Plan

of Merchandising Electrical Apparatus and Appliances—A Record Attendance Attests the Universal Interest Taken in the Goodwin Program by Manufacturer, Central Station, Jobber, and Contractor-Dealer Alike

The three-day convention of the executive of the National Association of Electrical Contractors and Dealers, scheduled to meet in Toronto, Oct. 14, 15 and 16, was postponed, owing to the epidemic of Spanish influenza. Special permission was obtained, however, to carry out the banquet part of the program, and on Tuesday evening, Oct. 15, some 275 electrical men, many from outside of Toronto, and a few from the eastern and western provinces, assembled at the King Edward Hotel to hear Mr. W. L. Goodwin.

The delegation from the National Association, in addition to Mr. Goodwin, included Mr. W. Creighton Peet, chairman of the National Association, Mr. James R. Strong, of New York City, chairman of the National Constitution Committee, and Mr. Samuel A. Chase, special representative of the Westinghouse Electric & Mfg. Co.

The banquet was held under the auspices of the newly formed Ontario Association of Electrical Contractors and Dealers. Senator Frederic Nicholls, president and general manager Canadian General Electric Company, whose influence and support were, in large measure, responsible for the success which attended the event, acted as chairman.

Senator Nicholls, in his introductory address, remarked that as a pioneer of the electrical industry in Canada, in which he had been engaged for thirty-five years, he felt honored to act as chairman at such a gathering. It was the largest and most notable gathering of Canadian electrical men in all his experience, and he congratulated Mr. Kenneth A. McIntyre, president of the Ontario Association, on the great success which had attended his committee's efforts. He then proceeded to point out what organization has done for Canada as a nation during the past four years. The war had introduced unprecedented conditions which had called for greater co-operation and more complete organization than had been known before. Such organizations as the Imperial Munitions Board had been formed and the resulting co-ordination of effort had worked most effectively to the benefit of Canadian industry, correcting the trade balance to a great extent, and producing wonderful prosperity. Such were the proven advantages of organization. Senator Nicholls said that having heard much of Mr. Goodwin's plan of organization for the electrical industry, he had come prepared to listen to Mr. Goodwin himself, with an open mind.

Mr. Goodwin's Address

"We have two very important jobs before us—we as electrical men. Our first job is to win this war, and that we are going to do without any shadow of a doubt, as we have the best organization in the field to do the job. It is said that food will win the war, but this is not so. It has been said that men will win the war, that money will win the war, that materials will win the war. These are catchy statements that sound all right, but the thing that will really win the war is organization, made up of all these things together. Next to the winning of the war we have the greatest responsibility, perhaps, of men of any industry, in the serving of the great masses of the people with electrical necessities and conveniences. No other industry contributes to such an extent to the progress, the success or the happiness of the people as does the electrical industry. Any other single industry might be left out of this war and the war would go on just the same, but take away the electrical industry and everything would stop immediately. Other industries make much of their contributions to the war—the automobile, the food and other industries tell us what they have

not but we are doing our work in silence and we will receive our just reward in due time. To the electrical people have been delegated the greatest responsibilities of serving the public, but I feel that in the past we have served them quite too well. Our effort has been selfish and individual. The great majority of electrical men do not realize their responsibility to the public; their sole idea is to profit. We give a great deal of time and money to charitable work, but do we realize that through the facilities which our industry offers human efficiency can be increased perhaps many hundreds of times, and that beyond the personal profit is the greater responsibility of serving the public. I do not know much about electrical conditions in Canada, but I do about the States. We have made very satisfactory progress. We are dealing with an unknown quantity and a great deal of credit is due to the pioneers, but we must do more. It is not generally known that the public has not been sold the electrical idea. Electricity in its various forms has been sold as a luxury. True, it has come into our industries as a necessity for lighting and transportation, but so far as its general use in the household is concerned, it is still considered a luxury. In the States, with a population of approximately 100 millions, the gross sales of our central stations approximate $300,000,000 per annum, or a per capita consumption of $3.00. In manufacturing, installation, and so on, the gross annual business is $500,000,000, making a total of approximately $800,000,000 or $8.00 per capita. This amount was no doubt exceeded during 1917, but when you consider that with perhaps three or four hundred thousand

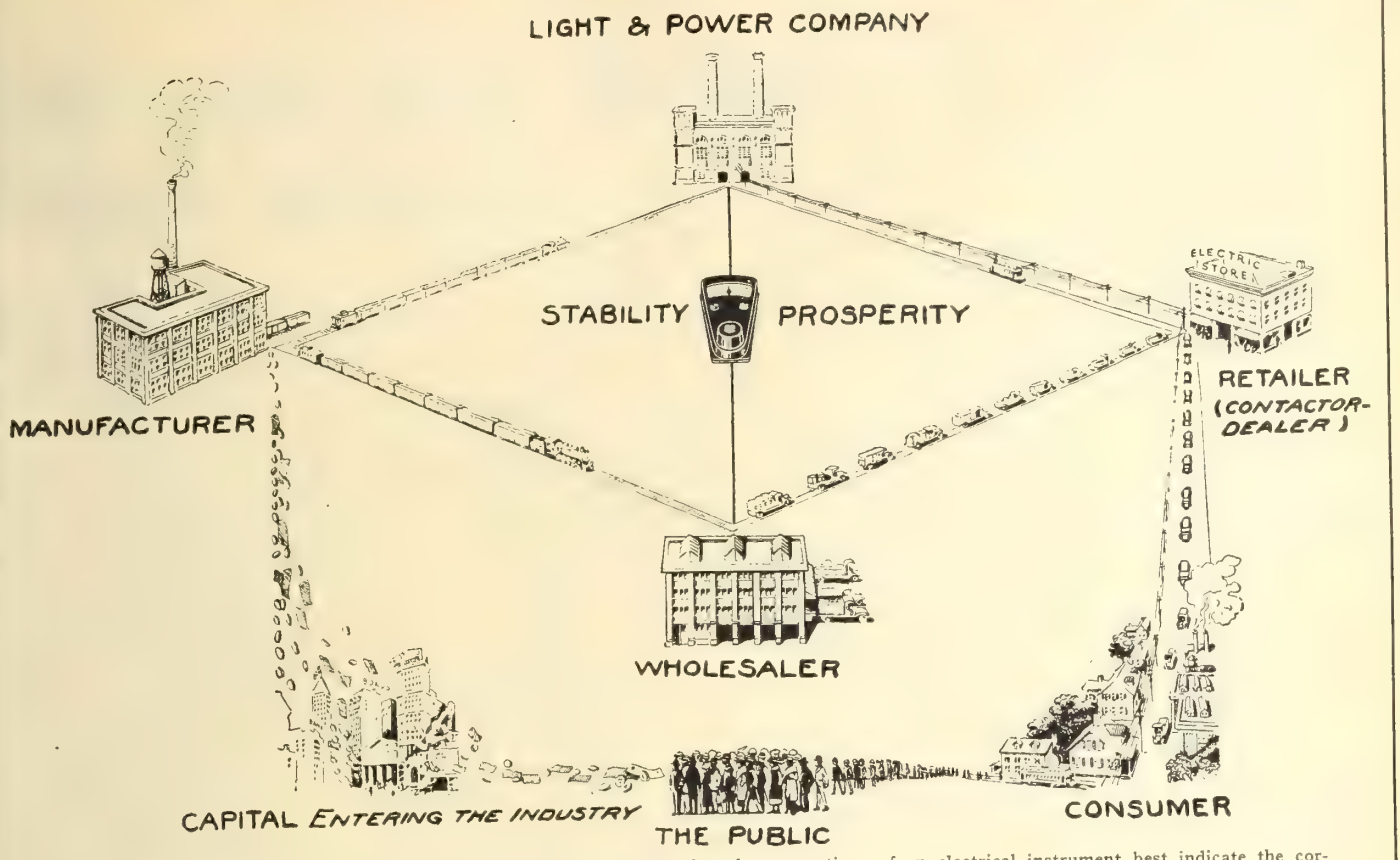
engaged in the industry we are only able to produce $800,000,000, and that the automobile industry exceeds the electrical industry by five or six times, then I say that as electrical people, we are not doing as well as we might.

"Our effort has largely been individual, and so believing I gave considerable thought to the question and made suggestions, and did some organization work in my own district, the Pacific Coast. There we had only a per capita consumption of $5.00 per capita, but we got the electrical people together, and in five years this consumption was increased to $30.00 per capita. If that rate could be extended in the States then we would have a gross annual business of $3,000,000,000 per annum, and all would participate in the rewards."

Mr. Goodwin said that the great difficulty was that the functions of the various branches of the industry had not been properly defined, that the manufacturer and central station had not assisted the retailer, but that the latter had actually been in competition with him, with the result that whatever business he got was at a low rate of profit. He referred to his own experience in the jobbing business and related how through co-operating with the retailer he had increased his profits in the ratio of 5 to 3 by increased volume of business and reduced overhead, while actually selling his goods at a lower rate. "I figure," he said, "that we are spending, in the U. S., perhaps ten or fifteen million dollars per annum to try and sell our products. If the same amount were expended through organizations co-operating in scientific distribution, it would easily raise our business to two or three billion dollars per annum in five or ten years."

"People are generally suspicious at first, this being particularly true of the electrical contractor. He has struggled with these obstacles for years and can't believe that jobbers and manufacturers, or central stations, are susceptible to change of policy. Since the plan was started in the States, however, hundreds and hundreds have changed and adopted an ethical policy of retailing, and it is working out. People are willing to try things to-day that they would not try a few years ago. Our campaign must be one of education. We must make business men out of the retailers, and when this is done you will find that many of the difficulties will have disappeared."

Driving around Toronto Mr. Goodwin had not been favorably impressed with the type of electrical stores. "There should be two or three hundred beautiful electrical shops in a city like Toronto. Of all the great industries in the world we are the only one that does not know what we are selling. We are selling an unknown quantity. We have not sold the electrical idea. There has been too much complication in our policies and too much effort expended in getting after unprofitable business. Our method of pricing in the electrical business is most unscientific. The value of the service rendered by the various factors has never been determined. No one seems to know the value of the service of retailers, whether it should be based on averages or sales of each commodity. We must have a scientific basis of price making before our distribution can be satisfactory. Price should be based on factory cost, plus reasonable profit, plus the cost of service rendered to the public. To my mind, a scientific price schedule for the sale of our commodities is required."



Mr. Goodwin pointed out the great difficulties which have arisen through lack of proper standardization. In the case of transformers, for instance, a legion of different types is required to supply all the various voltages, frequencies, etc., and there are some 5,000 different devices that may be used when wiring a building according to the choice of the architect or engineer. "Fortunately, through necessity of war, we are told we must conserve, and perhaps when we get through, we may have 300, instead of 5,000. We are being taught the lesson of co-operation and we are going to simplify our problem of manufacture and distribution.

"We have in the electrical industry a lack of proper organization in the four main branches. We have a lack of organization in the industry as a whole."

Mr. Goodwin proceeded to make same remarks on the value of organization, and told how the Wheatstone bridge had appealed to him as a particularly good illustration of how the various factors in the electrical industry should be co-ordinated. In this regard, he said:

"When Christie invented the Wheatstone Bridge in 1833, he little dreamed how significant it would become to the whole electrical industry. To-day it represents the scientific distribution in electrical merchandizing, and a brief study of the diagram will indicate how close this analogy really is. How particularly appropriate it is that the electrical connections of an electrical instrument best indicate the correct commercial relations in the electrical industry.

"The battery, the source of energy, represents the public, whose investors furnish the capital for all branches of the industry. This capital, the manufacturer converts into generating and distributing equipment for the central station or industrial plant, or into appliances and supplies. His sales diverge as shown in the diagram, dependent upon the principal class of product utilized by each branch. The central station has electric service as its principal product which, it will be noted, is used through the wiring installed principally by the contractor-dealer. The wholesaler has as his principal function problems affecting wholesale electrical

The Human Wheatstone Bridge—"How particularly appropriate it is that the connections of an electrical instrument best indicate the correct commercial relations in the electrical industry."

merchandizing. He makes contact with the central station or the contractor-dealer in passing to the consumer. The contractor-dealer thus becomes the point of retail contact of the manufacturer, central station, and wholesaler with the consuming public which, by the way, following the circuit, brings us back to the negative side of the battery, thus completing the analogy.

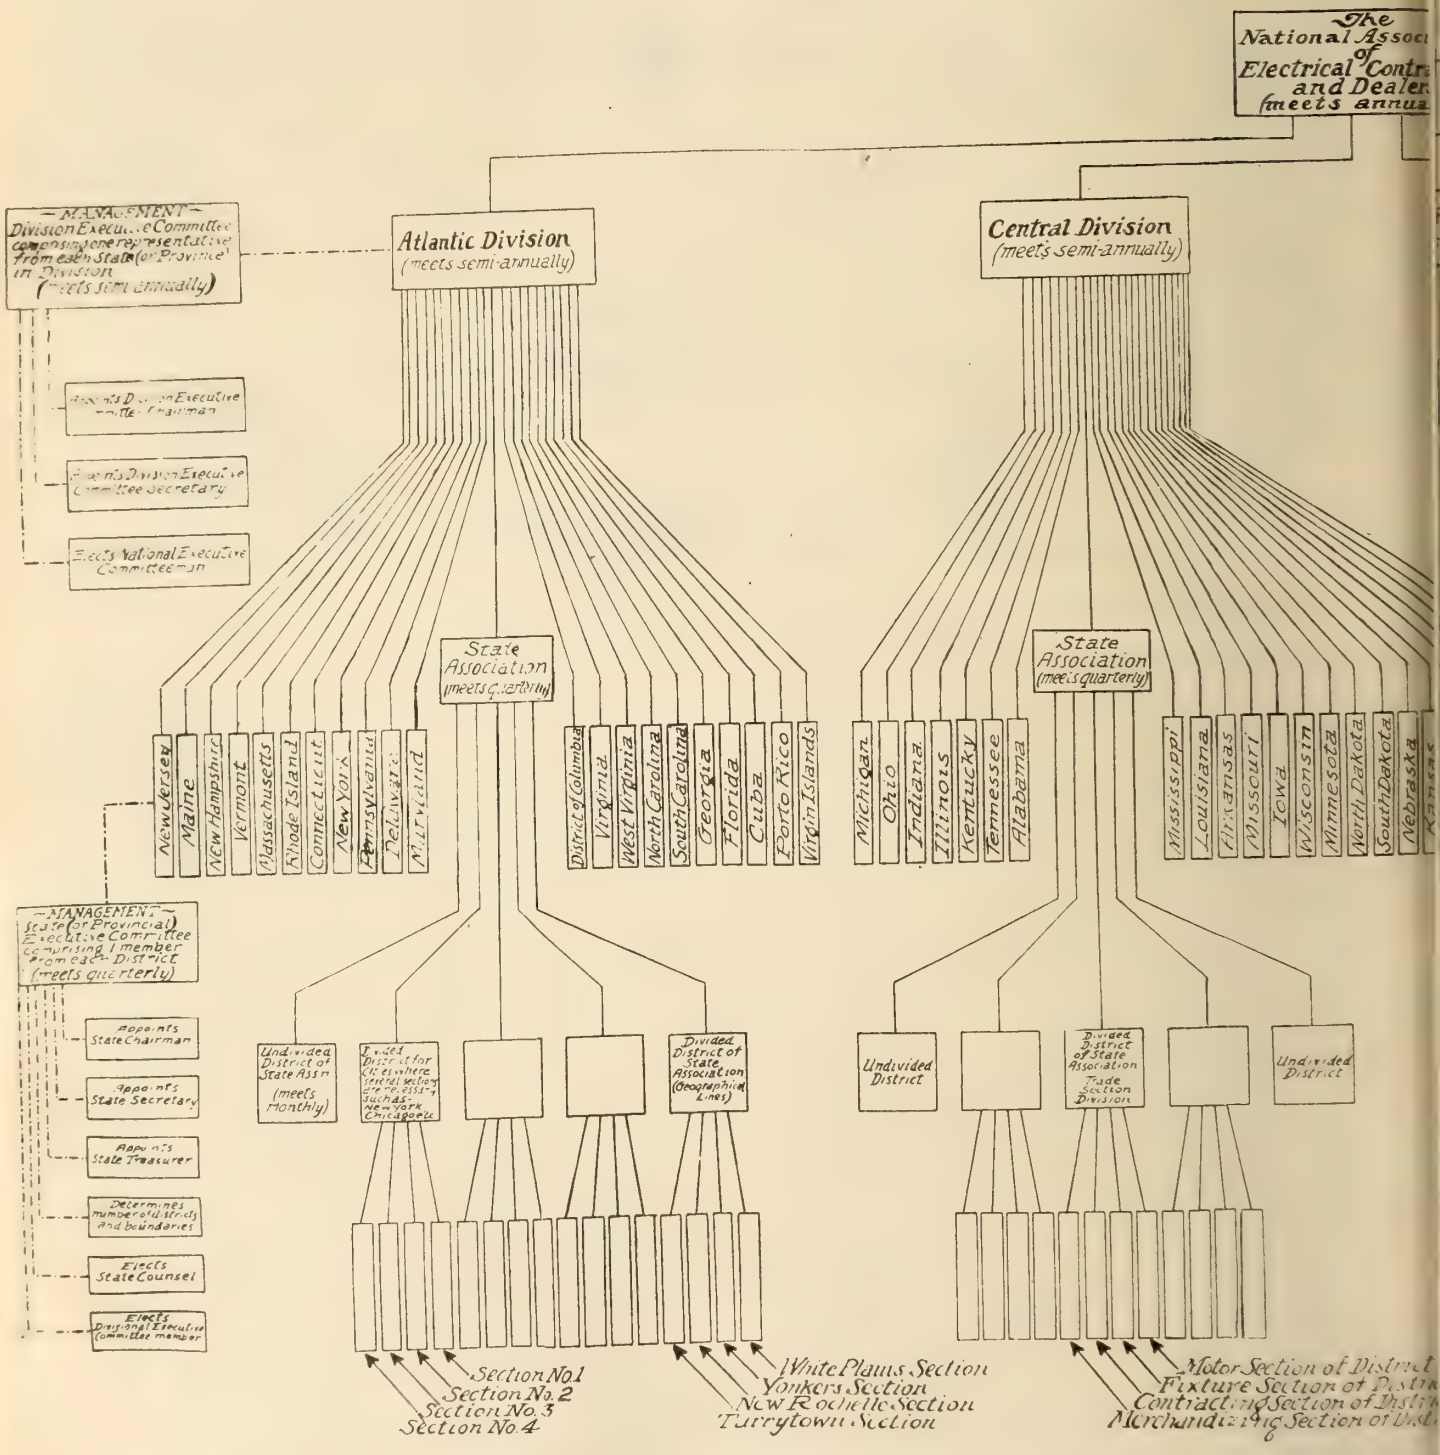
Nothing in the diagram indicates, nor is it the intention to restrain in any form, either of the interests referred to in performing the function of another, but due regard to the interests of all should be recognized in order that the scientific plan of merchandising under the Wheatstone Bridge principle will not indicate on the galvanometer such an unbalanced condition as now exists.

"When each interest operates with due regard to the interests of the others, the galvanometer will indicate at zero, an evidence of a balanced condition, which, when applied to electrical merchandizing and the electrical industry is reflected as stability and prosperity.

Solving the Problem of Distribution.

"With this explanation, you may now even ask the question:—How will the Wheatstone Bridge principle of electrical merchandising solve the problem of distribution and remove conflict of trade interests? My answer is:—It will not, unless applied by each individual concern and recognized as fundamentally correct by each branch of the industry. So this Wheatstone Bridge plan of merchandising is submitted as a scientific instrument analogous to the mariner's compass with the hope and belief that it will eventually be so recognized by the captains of the electrical industry.

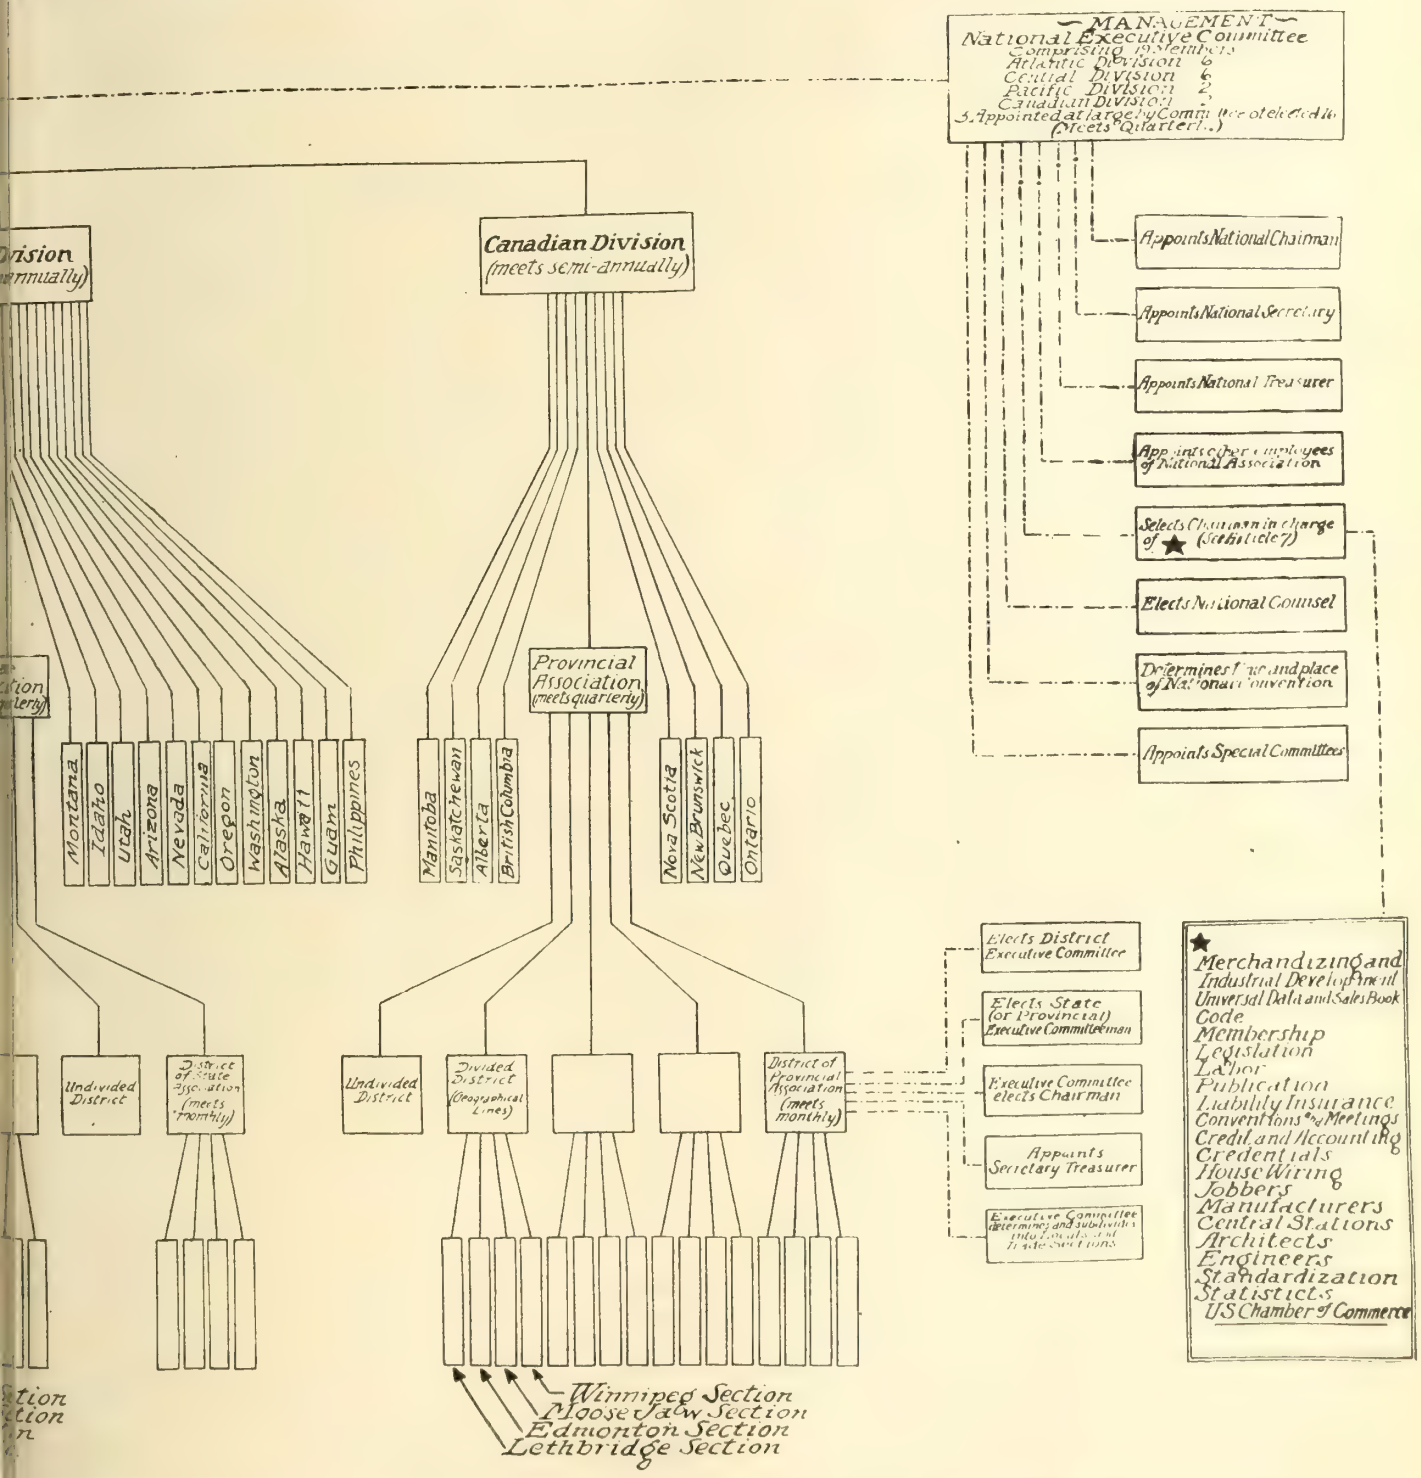
A compass, in itself, does not navigate a ship along the right course, but it enables the captain to direct his ship along not only a safe course, but as well over the shortest and best route to his destination. So the Wheatstone Bridge when applied to wholesale or retail merchandising, should serve as the "compass" of our industry, enabling us to readily understand "Navigation" as applied to our intricate commercial problems of merchandising and distribution, causing us to navigate our commercial ship not only along a course free from the submerged rocks of friction and failure, but as well over a course marked with beacons indicating co-operation, organization and co-ordinated effort. When the galvanometer on the bridge indicates zero it will reflect to the industry in the form of stability and prosperity.



"Better electrical merchants will mean better business for all of us—contractor, central stations, jobbers and manufacturing alike. A sound merchandising plan that will improve conditions in the retail selling field is bound to benefit in general every group and individual in the industry. But in addition to the broad results that will come in this way, the movement can offer some very definite benefits to the lighting company, the wholesaler and the manufacturer. And the plan should be looked at from all of these viewpoints, for in this matter of retail merchandising lies the solution to a lot of the problems that have been confronting the industry as a whole.

"The central station, be it privately or publicly owned, for example, wants security of public opinion and increased kilowatt-hour business. The plan insures these very things for the central station.

"The jobber wants larger volume of sales, security of his position in the trade and with the manufacturer, better credit conditions, better collections and his customers to be better business men. The plan offers these to the jobber.



"The manufacturer wants simplification of his selling problem, lowered cost of distribution and selling, standardization and wider use of his products and security for his

business, and these are the offerings the plan holds out to the manufacturer.

"The contractors, therefore, in asking the sympathy and interest of the other branches can themselves take pride in the fact that they are getting ready to go before the industry with a plan which offers a great deal for the lighting company, the jobber and the manufacturer, if each of these groups will study, understand and apply it."

In conclusion, Mr. Goodwin said: "I appreciate very much this opportunity of addressing you, particularly as the invitation has come from Senator Nicholls, and I am sure he will be a supporter of any plan you may decide upon. I do not say that the electrical men of Canada should get together on this plan, but they should get together on some plan and work it out."

Mr. Chase Endorses the Plan

At the request of Senator Nicholls, Mr. Chase, special representative of the Westinghouse Co., addressed the meeting. Mr. Chase referred to the excellent work being done by Mr. Goodwin and his plan of education, stimulating the various branches of the electrical industry to get together and devise ways and means whereby better merchandising methods may be used. He urged all to have confidence in Mr. Goodwin and the plan of the National Association of Electrical Contractors and Dealers for re-organization, and not to lose time by asking each other: "What's the ulterior motive?" because the plan, if in operation, would be of benefit to all in the electrical industry—manufacturers, central stations, jobbers, contractors and dealers—and to the public as well, for the reason that the lesson they are endeavoring to teach is: "How can we most economically sell electrical merchandising goods through the natural channels of distribution? To depart from these natural channels would be as foolish as trying to change the flow of the St. Lawrence River.

Mr. Strong on "Organization"

Mr. Chase was followed by Mr. Jas. R. Strong, of New York City, who dwelt on the subject of "Organization," In order to give his audience a clear understanding of the situation he proceeded to give a little history regarding the National Association, telling how the beginnings of the present organization were formed in 1890 in New York City with a membership of eleven; how it had been enlarged to a state association in 1905; and how in 1910, still finding the organization inadequate, the New York State association had been instrumental in getting a number of prominent electrical contractors together and forming a national association. This association had made progress and in 1916 reached a membership of 1,500, covering most of the states of the Union, but still its scope was too limited, representing not 10 per cent. of the retailers in the electrical business. The officers were busy studying the problems of its improvement, "when suddenly out of the Golden West came the Moses who was to lead us out of our difficulties." This Moses (Mr. Goodwin) attended a meeting of the executive last June, when he presented a plan which was enthusiastically received. As a result a National constitution committee was formed, consisting of Mr. McClary, of Detroit, and the speaker, and to it was consigned the duty of revising the existing constitution.

Mr. Strong pointed out that there were two main differences between the old and the new constitution. The first change was the creation of an associate membership, in order to bring into the association those who did any retailing of electrical merchandise. To suit this action the name was changed to the National Association of Electrical Contractors and Dealers. This associate membership consisted of those who carried on electrical merchandising as a department of their business—jobbers or central stations who retail, and department stores with electrical departments. The member was one who was exclusively a contractor and dealer.

The second step was to adopt the principle of paying dues in accordance with the amount of business done. The members had been classified in groups from "A"—less than $12,000—to "J"—over $500,000—and each paid in proportion. Further classes had since been added, the highest now being "over the million." The contractor or dealer was permitted to classify himself, based on his sales during the previous calendar year. The object of this action was to interest the small contractor or dealer, and leave the membership of the association open to him for a small fee, and the scheme was working out very satisfactorily.

Plan of Organization

Mr. Strong then referred to his organization chart which is reproduced elsewhere on pp. 30 and 31 of this issue—a new one to which the Canadian Division had been added. He pointed out that the reason for making the four divisions was that members might meet together at centres near which they were located. There would be two meetings of the divisions, and one national meeting each year. The divisions were sub-divided into state associations, the provinces of Canada being considered as states for purposes of constitution, and there was a further sub-division into districts, if necessary. Provision was also made to sub-divide the districts into sections, such as motor, fixture, contracting, etc.

In the distribution of data, etc., the channels worked downwards from the National Executive to the section, while the method was reversed in the collection of fees, the money passing up through the district, state and division, each appropriating it proper share. To provide for proper representation, there would be six committeemen elected to the National Executive from each of the two larger divisions, the Atlantic and the Central, and two from each of the two smaller divisions, the Pacific and the Canadian. The state associations in turn elected committeemen to the divisions, and the districts to the state associations.

Mr. Strong also referred to the special committees which had been formed to collect and distribute information that would be useful to all the members—such as industrial development, universal data and sales book, national electrical code, membership, legislation, publication, liability insurance, conventions and meetings, credit, credentials, house wiring, merchandising, etc. All this organization work had been accomplished in a short time, and there were now ten state secretaries giving their entire time to association work. It was held that these secretaries should be paid men; past experience shows that in no other way could the work be carried out satisfactorily. The secretaries attended to the technical and detail work, while the officers were responsible for the policies. At the last meeting of the Executive Committee, the appointment of a general manager of the National Association had also been authorized. Mr. W. H. Morton, formerly of the J. & M. Electric Co., of Utica, N. Y., and who had also been secretary of the old association for fourteen years, was chosen for this position.

Broadly speaking, the fees collected were used to increase the membership and to discover and assist those members who were not carrying on their business properly, sending them information and having experts call upon them to discuss their problems and point out how their methods might be improved. To assist in this object, a questionnaire card had been used with a number of enquiries as to methods, etc.

Another question which had come before the National Executive Committee was that of establishing a Bureau of Education and Research, and the speaker felt sure that at

the next meeting of the committee this step would be decided upon. By means of this Bureau it was hoped to interest those outside the association. It was also its object to educate the electrical retailers and the general public in the economical and safe use of electricity and electrical devices, to prevent the danger of fire through careless handling, and to promote the conservation of electricity during the war, to compile and distribute data on the cost of operating appliances, safe installation, etc.; and to compile this information in such form as to be readily available for making sales.

In closing, Mr. Strong made a few remarks on the value of organization, pointing out that it produced good fellowship and presented a means of mutual education. "None of us," he said, "are too old to learn something from organization."

Mr. Hayward Speaks for Vancouver

The chairman next introduced Mr. E. C. Hayward, of Victoria, B.C., Vice-President of the British Columbia Association of Electrical Contractors and Dealers. Mr. Hayward extended to those present the hearty greetings of the association he represented. He said that his association had been in existence for the last two years, and that a month previously they had resolved to affiliate with the National Association. He therefore tendered to Mr. Peet, its chairman, their offer of affiliation. Mr. Peet, in replying, expressed much pleasure in accepting the offer, and said he only regretted the National Executive Committee was not present to receive it.

Kenneth A. McIntyre—The Man Behind the Gun

In introducing Mr. Kenneth A. McIntyre, president of the Ontario Association of Electrical Contractors and Dealers, Senator Nicholls said that Mr. McIntyre had worked very hard indeed in order that this notable gathering might be an accomplished fact, and that supreme credit was due him for his efforts. Mr. McIntyre modestly deprecated the chairman's flattering remarks, and explained how it had been through the influence of Senator Nicholls and his invitation to Mr. Goodwin to address the gathering that such success had been made possible. He explained that his association had followed practically the same plan of organization as the National Association, only adjusted a little to suit the Ontario Act. Envelopes containing full information and directions as to joining the Ontario Association had been provided for the use of non-members and he trusted that a large number of them would join right on the spot. In closing, he tendered to Mr. Peet his association's offer of affiliation.

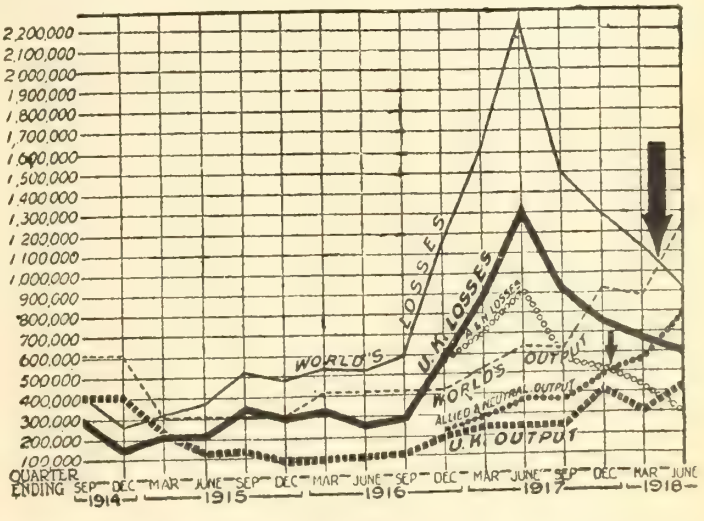
Mr. Peet, in reply, said that he felt in a way that he was making history. He took credit to himself for inviting Mr. McIntyre to Detroit to the National Executive Committee meeting, and said that at that time he and his associates were very much impressed with Mr. McIntyre's enthusiasm for the movement.

PHOTOGRAPHS OF THE BANQUET

Photographs of the Goodwin banquet, 11 x 14 in., mounted, may be obtained from the president of the Ontario Association of Electrical Contractors and Dealers, Mr. Kenneth A. McIntyre, at $2.00 each; by mail 10c extra.

The Regina street railway system shows a deficit of $42,405 for the first nine months of the year, according to a statement just prepared. The electric light department shows a deficit of $16,490 for the same period.

Hydro Development on Riviere des Prairies



A company, headed by Senator M. J. O'Brien, of Renfrew, with Messrs. Quinlan and Robertson, contractors, Montreal, have sought authorization from the Quebec Government to proceed with a Hydro-electric development on the Riviere des Prairies, Island of Montreal. The preliminary plans, drawn up by Mr. Henry Holgate, consulting engineer, Montreal, provide for a development of 40,000 h.p. Federal sanction has already been obtained, subject to modifications of the original plan, and provincial authority is required for use of the bed of the stream.

It is proposed to construct an arc shaped dam, starting on the Montreal side below the Viau bridge, and continuing in a straight line on the other side of the river to Sergeant Island and to the north shore of Visitation Island; from there the dam will run to a point just below Cheval de Terre Island. The power house will be on the south shore of Jesus Island, and the preliminary plans provide for nine units.

The project will raise the water level some 15 feet and will interfere with the sewer outlets of Montreal. When representatives of the company asked the Quebec Government for the requisite authority for the work, the city of Montreal raised the question of damage to the outlets. The company's representatives expressed a desire to meet the city on this point, and the Premier therefore suggested that the company and city get together and settle the question of reconstruction and financial responsibility. When this was agreed upon, the company should again see the Government for permission to proceed with the scheme.

The Naval Situation

The diagram below, which is taken from the Daily Mail, of London, England, illustrates very clearly the trend of the world's shipping output, and the losses due to enemy submarines, from September, 1914, to June, 1918. It will be

observed that at the point of time marked by the arrow, in April or May last, following a comparatively sudden decrease in losses, the output rose above the sinkings. In allied and neutral shipping, the output began to overbalance the losses at the earlier date marked by a smaller arrow. Now that we have the confidence of a satisfattory conclusion of the war, we can look back and consider the seriousness of the situation which confronted us when the Hun's piracy had reached its peak in June, 1917. At that date the sinkings of shipping belonging to the United Kingdom alone were more than double the world's total output and about five times the British output, while the world's production was considerably less than one-third of its losses. The British position, even as late as last June, does not appear very satisfactory

Manufacture of Heating Appliances is Restricted in the United States

The War Industries Board of the United States, in order to conserve essential materials and labor, to free capital tied up unnecessarily in manufacturers' and merchants' stocks, and to simplify and standardize factory production, has issued a schedule for manufacturers of electrical appliances which calls for the discontinuance of the manufacture of the following:

List to be Discontinued:

Carburetor heaters, hand-wheel heaters, in-take heaters, manifold heaters, primer heaters, blankets, robes, cigar lighters, frying pans, plate warmers, curling irons, saute pans, waffle irons, fluting irons, egg boilers, soup kettles, stew pans, corn poppers, hand dryers, hosiery forms, peanut roasters, transfer irons, vaporizers, varnish sprayers, entree dishes, cigar lighters for automobiles, bookbinding appliances, instantaneaus water heaters, automobile foot warmers, fudge warmers, vegetable dishes, and all Sheffield plated ware.

The schedule for domestic appliances (600 watts or less, except ranges) provides:

All appliances that are to be eliminated, but which are now in the process of manufacture or are completed in stock may be sold, but no more material for any of these appliances to be purchased except to balance up stocks on hand, and their manufacture is to be discontinued entirely Dec. 31, 1918.

Output to be Restricted.

Industrial appliances (over 660 watts).—Each manufacturer of the following appliances to restrict his output to the number of styles and sizes specified:

	No. of styles	Total No. of sizes
Convection air heaters	3	7
Confectioner's appliances	2	2
Corset irons	1	1
Matrix dryers	1	1
Tailor's irons, 12 lb. or over	2	4
Laundry irons, 7½ to 10 lb.	1	2
Gluepots (no aluminum pots to be made)	1	3
Circulation water heaters	2	11
Immersion water heaters	1	8
Round disk hot plates, opencoil type	1	4
Dound disk hot plates, open coil type	1	4

Steam boilers: To be sold only where the electrical energy is generated from water power and there is a surplus of such energy available.

Restaurant equipment—Each manufacturer of the following appliances to restrict his output to the number of styles and sizes specified:

	No. of styles	Total No. of sizes
Bake ovens	1	5
Broilers	2	3
[illegible]	2	3
Toasters	2	2
Hotel ranges	1	2

In the appliances not discontinued, the Conservation Division has cut out 691 different styles and sizes. For instance in chafing dishes, there were thirty-six styles and but three will be allowed; of electric teapots, twenty styles and one allowed; of toasters, ten styles and but two allowed. Manufacturers are to discontinue silver plated and copper finish appliances from the styles and sizes they will continue to make.

None to Add to Style.

In no case is any manufacturer to add to the number of styles and sizes that he is now making.

Each manufacturer of the following appliances to restrict his output to the number of styles and sizes specified:

	No. of styles	Total No. of sizes
Chafing dishes	3	1
Percolators with faucets	3	2
Percolators without faucets	3	2
Samovars	1	1
Nursery water heaters	1	2
Teapots	1	1
Hot-water kettles	1	1
Ovens	1	1
Reflector heaters	2	2
Toasters	2	1
Toaster stoves	1	1
Convector heaters	1	1
Disk stoves	2	2
Fireless Cookers	1	2
Flatirons, 7½ lb. or less	2	2
Grills	2	1
Heating pads	2	2
Hair dryers	2	*1

*1 in each style.

Ranges: No more than six different ranges covering both styles and sizes to be made at any one factory, and none to be made at any factory that is not producing ranges at this date. Nickel plating and fancy ornamentation to be eliminated.

Electric Company Could Not Collect

Mr. Justice Demers, in the Superior Court, Montreal, has dismissed two claims of the Vaudreuil Electric Co. Ltd. for $23,456.40 and $10,046.55 against Curtiss and Harvey (Canada), Limited, in liquidation. The Vaudreuil Electric Company had contracts for these amounts with the Curtiss & Harvey powder plant, at Dragon, prior to the explosion of last summer, which destroyed the plant completely. Following the disaster, the company filed claims with the liquidator of the Curtiss & Harvey Company for the above sums. The liquidator opposed the claims on the ground that the disaster was of force majeure, and that the firm in liquidation was not liable. This contention was upheld by the court, which declared that the accident could not be attributed to any fault of the Curtiss & Harvey Company.

Mr. R. F. Irvin has been appointed assistant to L. D. Calhoun, the advertising manager of the Square D Company of Detroit, manufacturers of Square D Switches. The appointment became effective October 3rd. Mr. Irvin was formerly branch advertising manager of the B. F. Goodrich Rubber Co., in charge of advertising for the Philadelphia territory.

What the Coming Victory Loan Means to Every Class in Canada

By Mr. E. R. Wood

One year has elapsed since we prepared to subscribe the first Victory Loan (our fourth loan) issued in November, 1917. We then realized clearly, and for the first time, that Great Britain had reached the point at which she was compelled to borrow funds in the countries in which she is making her war purchases. This was, and is, an extremely important consideration for Canada, because our activities, prosperity and assistance in the war, depend almost entirely on our ability to market our factory and farm products in the United Kingdom.

When we were asked to subscribe to the Victory Loan, we were enjoying what we may term the prosperity of war, due to the vast volume of orders placed in Canada by the United Kingdom. These war orders were, and are, the backbone of our general position.

We were faced also with certain results of the entry of the United States into the war. The most serious was the closing of that money market to our financial requirements. During 1915 and 1916 Canada was able to subscribe the greater part of its war loans, leaving a portion of them for subscription in the United States which also financed a large part of our ordinary requirements. The new situation created the necessity not only of making Canada's 1917 Victory Loan an unqualified success, but also of financing the Provincial Governments, municipal and corporation requirements, in addition to taking up maturing obligations in the United States. Those obligations in ordinary times, would have been renewed in that country.

With the subscription of a large Victory Loan in prospect, and these serious financial factors governing the situation, the market for bonds other than war issues was at a complete standstill, and the outlook was not good.

The trend in the financial position in the United States during the past 3½ years so far as Canadian borrowings are concerned, is shown in the following table:—

1915	$110,508,000	$64,094,000	58
1916	80,014,000	57,610,000	72
1917	32,404,000	8,425,000	26
1918	61,005,000	1,700,000	2.78

When the United States entered the war, in April, 1917, we were therefore faced with two important factors, namely, that Great Britain could not pay cash for her purchases in this country and that the United States could not longer help to finance Canada.

That was the delicate and dangerous situation. The success of the Victory Loan met that situation completely.

Cause of Great Business Activity

The great business activity resulting from the issues, created additional funds for investment. In due course, it afforded sufficient surplus funds in our own country to finance, not only the requirements of war, but also credits for the United Kingdom and loans to our provincial governments and municipalities. During the first eight months of 1918, Canadian investors having taken the large Victory Loan of last fall, have also been able to finance our province and municipalities to the extent of $60,000,000, as mentioned above. In addition $50,000,000 of the 1917 Victory Bonds have changed ownership, being bought by bona fide investors from holders who found it necessary or desirable to lessen their holdings. This wide and continued interest in the Victory Bonds is no doubt due to some extent to the fact that the Canadian people have been educated by the Victory Loan campaign to invest their savings in Dominion Government Bonds.

It ought to be clearly understood that in approaching our next Victory Loan, we are faced with an equally serious situation. Only by the complete success of our 1918 Victory Loan can we continue to finance our requirements and carry on generally in the way we have during the past seven months.

Gave New Lease of Life to Dominion

The remarkable over-subscription of the 1917 Victory Loan completely changed the uncertain outlook which prevailed when the Loan was offered to the public. It gave a new impetus to agriculture, commerce and prosperity. It invigorated our efforts in the war. It allowed, as already stated, our Provincial Governments, municipal and other borrowers to finance their requirements at home. In short, it gave another lease of life to the activities of the Dominion.

A Boon to Canadian Farmers

For the farmer, the Loan was able to finance the only purchaser who could buy his excess products, namely, Great Britain. In the fiscal year 1915, our farmers exported animal produce and agricultural products valued at $209,000,000. For the fiscal year ended 31st March, 1918, they exported no less than $740,000,000 worth of their output, the largest agricultural exports from this country on record.

Manufacturer Prospered by It

For the manufacturer the Victory Loan continued to give the best export market he had ever possessed. Canadian manufacturers during the fiscal year ended 31st March, 1915, exported $85,000,000 worth of merchandise. That period included nearly eight months of war. For the twelve months ended March, 1918, they have exported over $636,000,000 worth of merchandise, an increase in three years of $551,000,000, or 648 per cent. It is interesting to note in connection with these exports that since the Loan was raised, approximately $20,000,000 per month have been advanced to the Imperial Munitions Board at Ottawa for the purchase of Great Britain in this country. There have also been expended approximately $20,000,000 a month for other war purposes in Canada, including large purchases of farm products. This is a monthly total of $40,000,000 or, during the seven months from December, 1917, to June, 1918, a sum of $280,000,000.

950 War Contracts

While the entire farming community has shared in the war orders, all the manufacturers, naturally enough, have not been benefitted directly. Even so, contracts have been given to 950 manufacturers, and in July, 1918, 400 manufacturers were in actual contract relations with the Imperial Munitions Board at Ottawa.

Up to June, 1918, our manufacturers have produced over 60,000,000 shells, 20,000,000 fuses, 74,000,000 lbs. of powder and 50,000,000 lbs. of high explosives.

Of the 1,654,000 tons of steel used in our war work, 1,400,000 tons were produced in Canada.

Contracts have been let in Canadian shipyards for 90 steamships with an aggregate dead weight tonnage of 455,000 tons. These orders have a value of $71,000,000.

National war plants have been established at a cost of

$15,000,000 in Montreal, Renfrew, Trenton, Toronto and Parry Sound, where powder and high explosives are made, fuses loaded and forgings produced and aeroplanes built. These plants have been given their contracts by the Board at the same prices and on similar terms as the independent makers of munitions and they have already amortized their cost to the extent of $10,000,000.

Large quantities of fir and spruce are being purchased by the Imperial Munitions Board in British Columbia for aeroplanes. The Board now has 67 logging camps in operation.

Made Possible Big U. S. Orders

As a collateral advantage to Canada, by reason of the development of capacity to manufacture in a large way, the United States have found it to their advantage to place orders for the production of munitions in Canada to an important extent; the United States supplies all the raw materials, Canada supplying the labor and experience. The benefit of this to the United States, as well as to Canada, will be understood from the fact that the 75 millimetre shell, which is the size for which the largest number of orders have been placed, both in the United States and Canada, were produced in Canada last month in a quantity in excess of the total production in the United States. The production of this size of shell in Canada now on account of the United States Government is 255,000 per week and is steadily increasing.

As a further evidence of the interest of the United States in the developed capacity of Canada, representatives of the marine section of the Imperial Munitions Board were asked to attend a conference called by the Emergency Fleet Corporation of the United States in Philadelphia on the 21st of June, for the purpose of ascertaining what assistance Canada could give to them in the production of marine engines and marine supplies. Already large orders have been placed in Canada for marine castings and winches, and general supplies for the shipbuilding program in the United States. Of course, it is obvious that this business from the United States will have a marked effect upon the exchange situation, as the money is practically all for wages, as the material is practically all from the United States.

Labor Demand Maintained

The success of the Victory Loan insured a continued demand for all kinds of skilled and unskilled labor. High wages have been received and have helped to cope with the increased cost of living resulting from the effects of war for a long period. Agricultural, factory and other labor have earned good wages, giving a margin for saving.

The placing of $400,000,000 by the subscribers to the Victory Loan, in the hands of the Government, enabled the authorities to continue to finance the basis of our prosperity, namely, war orders from the United Kingdom. It assisted them also, to a marked degree, in seeing that Canada does its full part to support our troops at the front, to help feed the Allies, and to bring the war to a successful conclusion as speedily as possible.

The flotation of the Victory Loan, in short, has kept in motion and in good running order the complex, economic machinery of the country.

New Loan Must Be Over-subscribed

Now with regard to Canada's 1918 Victory Loan, it is imperative that it should be well over-subscribed and even more successful than the 1917 Loan.

This is necessary, firstly, because we cannot continue to do our part in the war without the required funds; secondly, because we cannot obtain those funds unless the national activities are maintained at high pressure; and thirdly, because that end cannot be accomplished unless we finance the national activities which have such a vital bearing on the international situation and the conclusion of the war.

It would be a disastrous error were we to be lulled, because of our prosperity, into a misunderstanding of the real situation. It cannot be emphasized too frequently that the safety of our national structure and our participation in the war, depend entirely upon the results of the 1918 Victory Loan.

Our Prosperity Depends on It

Our prosperity during the past year was a direct result of the response to the loan issued last fall. The continuance of our prosperity during the coming year will depend upon the degree of success achieved by the Victory Loan of 1918. Unless we do even better than a year ago, we will jeopardize the prevailing prosperous conditions and activities which, in turn, allow us to participate freely in the conduct of the war.

There is not a legitimate reason why on this occasion we cannot better the results of the previous Loan. We have done well in the past, both in the aggregate and per capita. At the same time, we realize that our position in Canada is a fortunate one, compared with that in European countries which are in the immediate zone of war. No one can reasonably contend that we have yet achieved the best possible results in regard to the raising of War Loans. The evidence of better latent efforts are apparent on every hand. It remains only to organize and give effect to them. For example, while the total bank deposits in Canada on the 30th of November, 1917, were $1,547,000,000, they had decreased to only $1,541,083,788 on 31st July, 1918, a comparatively trifling decline of under $6,000,000, while the deposits in Canada at 31st July, 1918, are $160,000,000, greater than 31st July, 1917. This excellent record was achieved despite the subscription of the 1917 Victory Loan of $416,000,000, despite the absorption of $50,000,000, of those bonds sold by holders during this year, who desired to realize, and despite the purchase by our investors of $60,000,000, provincial and municipal bonds. These are substantial indications of Canada's ability to subscribe another large Victory Loan, because the national activities allowing the nation to make such a record as outlined above, have continued in a marked degree, making it possible to repeat and better the 1917 Victory Loan and general record of the country.

We Must Finance British Purchases

Great Britain having borne a tremendous burden of war for four years cannot be expected to finance her war purchases in this country. The United States is perfecting a vast war machine. Her financial resources are required for that purpose and to place credits at the disposal of the Allies. It is necessary, therefore, that Canada should raise the funds required, not only to carry on our normal and war activities, but also to advance substantial sums to Great Britain for her purchases here.

While in the United States, the people have been asked to subscribe a Liberty Loan every few months, we, in Canada, have not been asked to subscribe a war loan since November, 1917, This is an enormous advantage in every way. The long respite from War Loan activities, has enabled the 1917 Victory Loan to be splendidly absorbed and distributed. Has in addition created a healthy market for provincial and municipal bonds, and has allowed business generally to proceed without the temporary halt which war loan issues always bring. Furthermore, it is not too much to say that the maintenance of the market price of the 1917 Victory Loan at the issue price and the recent advance in the issue price constitute a record in war finance.

If satisfactory results are achieved with Canada's 1918 Victory Loan, the funds raised thereby will supply our needs for another year. That is an additional reason why every effort should be made to make the Loan an unqualified success.

The Electrical Dealer from a Manufacturing Standpoint

By Mr. Samuel A. Chase*

In these days of reconstruction along almost all directions of human effort, it is not strange that a spirit of unrest should have found an entrance to the field occupied by the jobbers and contractor-dealers. Lawyers of the highest eminence are persuaded that both the practice of law as well as the law itself are facing changes of a radical sort. A diploma, a small black bag and a sympathetic, bedside manner no longer constitute the essentials of a profitable medical career. Merely to know that c-a-t spells cat does not necessarily qualify one to teach the fact to others. And precisely as law, medicine and pedagogy have a future entirely different from the recent past, so also is it most reasonable to believe that the same principle applies with equal force to the more complicated business of selling the product of a factory.

Change is the fundamental fact of economic progress. To recognize and accept the probability of a change is one-half of the problem; and to see its direction accurately provides the ultimate solution.

The inexperienced manufacturer of electrical appliances creates a sales policy of selling direct, forgetting the jobber, and contractor-dealer, and says they are useless. Cut them out; they are carbuncles on the commercial body; they are parasites; "they toil not neither do they spin." Many of you have heard this sort of statement. It pretends to be an argument, and poses as a demonstration. Being both loud and misleading it is the song of the siren in every sense so far as any useful purpose can be found. Nevertheless it has tempted many a manufacturer from the ship of safety and one glorious summer of success has induced a multitude of disastrous financial winters.

Nearly every commercial line has been attacked by the fever, with the usual losses to the manufacturer, and the injury of the distributor and seldom to the advantage of the manufacturer.

There is an old saying that "the longest way 'round is the shortest way home." Experimental short cuts often are costly. A multitude of greedy manufacturers have tried to sell direct at the jobber's price; a myriad of grasping retailers have tried to buy directly from the manufacturer, with the jobber's discount. So they lock horns over this trifling middle percentage and upset the stability of trade conditions very greatly to their own loss.

I am familiar with some of your problems; not all, not nearly all. But I know the confusion caused by the electric light companies when they sell electrical merchandising appliances at cost in order to increase the consumption of current. I know about the pit dug by the local contractor—into which he himself frequently falls. But although I know something of your "'hard trials and great tribulations," I know also that you should occupy an impregnable stronghold.

In the first place "possession is nine points of the law." You may say confidently with Napoleon "I am here. I shall stay."

Secondly, "in union there is strength," and you will impress others through consolidating associations, as an united body.

Any plan of reconstructing the method of selling electrical merchandising appliances through the co-operation and close alliance between the manufacturer, jobber, central station and contractor-dealer, distributing through natural and legitimate channels, will place the electrical industry in a better relation to the trade than ever before.

It will make close friends of those who have sometimes been active enemies. This would be no small accomplishment if there were nothing else; but it is only the first of a long list of benefits which will accrue, not only to the manufacturer, but also to everyone interested in the electrical industry. Why? Because the policy will give balance and stability to the commercial phase of the business. It will establish a relation which is an improvement on "live and let live" since it is based on the idea of co-operation—"live and help live."

Wrong Methods in the Past.

For several years, as you know, the condition of the electrical trade in some respects has been going from bad to worse. Not that we, as manufacturers, have not made money, or that the contractor-dealers as a class have been doing business at a loss. But any business which proceeds along other than sensible roads is conducted wrongly in that particular direction in which it diverges from the path of efficiency.

We know that you live under a competition so severe that only the most robust and aggressive contractor-dealer can survive. We know that the dealer is as necessary a part of the electrical trade as the manufacturer or the jobber in the sale of electrical merchandising appliances. And, with this knowledge set clearly before us, we propose to do our utmost to assist toward reconstructing the highway of business.

Where there is a rut, we'll get out of it; where there's a steep grade, we'll go around the mountain; where there's a chasm we'll bridge it; and where there's a long detour, we'll build a short cut.

In the grand orchestra of electrical business, the smallest retailer should find a place in which to play his piping piccolo and the manufacturer and jobber should co-operate.

But, gentlemen, there is one important number of an orchestra we must not forget; that is the leader. So why not assume the leadership of all the contractors of the United States united in one body?

If it is desirable, it may be feasible. If it may be feasible, it may be done. But it will not be done by merely talking about it, or wishing for it. There must be preparation; the music must be written; the instruments tuned and the performers trained. There must be team-work in the best sense. There must be mutual confidence, as well as individual courage. Utilize these qualities; combine them in the way that you can and you need have no fear for the result.

On the other hand, there is no folly greater than to fool oneself; and it is folly to assume that the distributor has a vested right to any business. He must make his claim good by performance and he cannot perform successfully without a clear knowledge of his powers and limitations.

The manufacturers and jobbers must get the dealer's lively sympathy and then his active co-operation and he must assist to create a demand for electrical merchandising appliances and do all the things which are vital and necessary to merit the business.

One of the principal criticisms of the manufacturer in

*Special Representative, Westinghouse Supply Department.

the past has been that the average contractor-dealer does very little to create a demand for the sale of household and other electrical appliances to the consumer. In other words, he is not a merchant.

If the contractor-dealer will become a real merchant, there is no department of selling in which the manufacturer and jobber will not be ready and anxious to help him. Suitable advertising matter will be furnished; salesmen instructed and attractive window displays suggested and the manufacturer, jobber, central station and contractor-dealer will go hand in hand down the road of business prosperity.

I believe it pertinent at this time to emphasize that the manufacturers believe that the electrical dealers have not been as active as they should be in the sale of motor-driven devices, and there is a great possibility in this field.

Take for instance, six of the commonest electrically-operated machines used in the home, i.e., the washing machine, the sewing machine, the ironer, the vacuum cleaner, the fan-motor and the polishing and grinding motor. All

BUY VICTORY BONDS
Are you SUBSCRIBING the way they are FIGHTING?

of these classes of apparatus have been developed to a high degree, are manufactured in very large quantities and should be universally used wherever electricity is available.

The fact that the electrical dealers have overlooked this possibility is noticeable since a number of new concerns have sprung up who do nothing but handle devices of this kind, adding to their line a full line of heating apparatus. Such dealers can now be found doing a profitable business. Their stock in trade consists of an attractive display room in a district frequented by women on their shopping tours, usually some advertising and in some instances, solicitation through the residential district.

The electrical dealer has been slow to get into this particular field and, I believe that in order to handle devices of this kind, he must have an attractive store, he must be in a position to do extensive solicitation, considerable newspaper advertising and render services from time to time in connection with such devices as he has sold.

It is true that either an attractive display room or else a system of house to house canvassing with samples furnished free of charge is necessary. Newspaper advertising has also been effective, if the advertisements are properly timed and carefully prepared. The question of service is furthermore necessary, but the successful electrical dealers make their service feature one for building up additional business. In other words, their service men who go out to repair or adjust any device sold, open up sales for other classes of apparatus. They distribute literature and report prospects to the office, which are followed up systematically and energetically.

A good illustration of this service feature is that pursued by a concern out west which has recently put on the market a farm lighting outfit. The sales organization of this company feels that they are just starting when they sell the farm lighting outfit. They follow up the prospects with all sorts of electric devices, such as fans, house pumps, washing machines, ironers, sewing machine motors and small motors for general power purposes. Their prospect becomes a regular customer for lamps. He, undoubtedly will make extensions in time in his wiring and will require supplies. Thus, they become the sole supplier of the farmer's needs along electrical lines. If more of the electrical dealers would pursue such a policy as this they would, undoubtedly, build this business up enormously.

It would pay the electrical dealers to get in touch with the manufacturers of small motors and electrically operated devices used in the home. On the most expensive of these, extension time payment plans are now worked out which enable the householder to finance purchases which he could not think of financing if he were required to raise the necessary cash.

This is the time of great economy. There are many tens of thousands of electrically driven washing machines being sold each year and this number is increasing in spite of the increased cost of living, due solely to the fact that they are reliable labor savers. Many women are dispensing with their laundress and either handling the washing machines themselves, or doing so through the maid of all work they usually employ. This means a direct weekly saving which will pay for an electrically-driven washing machine and ironing outfit, before many weeks pass by.

Likewise, in the sewing machine motor, there never was a larger demand than there is at the present time in connection with a large amount of clothes that are being manufactured and the enormous amount of Red Cross work which is being done. These same arguments apply to the other devices I have named, and there is no question in our minds but what the next two or three years are going to show an increasing demand for labor saving devices.

The electrical dealer has not been alive to this situation in many localities. Manufacturers have had to establish their own branches for retailing these electrically-driven devices and as indicated, a special class of labor has sprung up simply because the electrical dealer has not realized the opportunity and modified his business methods to meet this new condition.

Electrical manufacturers and manufacturers of motor-driven machines used in the household have worked out quite extensive selling campaigns, based on experience gathered in the field, which is all furnished to the electrical dealer gratis, as well as other literature and sales helps.

Exclusive of manufacturing, all business is divided into three principal parts—buying, selling and paying for something. If therefore your president was authorized to appoint a trade promotion committee, I believe excellent results could be obtained, this committee to be composed of four members or more; a distinguished buyer, a mature, widely popular salesman; a financial man of ripe experience and an experienced advertising man. They would be important men in the trade, no two of them connected with the same house, and the president, ex-officio would be a member of the committee.

Your trade promotion committee would have wide authority; no written reports to make, and its meetings would be frequent. It would receive suggestions thankfully from any source, but incur no displeasure for not using them. The cost of its operations would not be difficult to assess equitably, and also would be negligible as compared with the vast benefits, financial and moral, which should accrue.

Through this compact little committee you would find the means to combat successfully any apparent tendency to invade your logical right to an important place in the world's electrical business. You would be able to show greed how it over-reaches itself by injuring you and ignorance would be converted into a knowledge that the electrical contractor-dealer must not, in fact, cannot be ignored.

In short, if there should be a definite tendency on the part of the manufacturers and jobbers to eliminate the contractor-dealer in your particular branch, you occupy a peculiarly strong position which can be strengthened by maintaining the closeness of your union and by a systematic, persistent course of education to instruct those of whom you buy and those to whom you sell, in the invaluable nature of your services.

Service at Cost for Toronto Railway

Mr. Herman H. Pitts, of Ottawa, a director of the Toronto Street Railway, is at the head of an organization to be known as "The Association of Holders of Public Utility Securities." It is hailed by the newspapers as an attempt to ward off the taking over the railway by the city when the franchise expires in 1921. The association has for one of its aims the inauguration of "service-at-cost" or in other words, a sliding scale of fares to increase or decrease proportionately with the changes in the cost of service.

Peterboro Railway Extension

The Peterboro, Ont., street railway will be extended from Charlotte to Patterson street; two more cars added and the service improved generally. After these improvements there will be no more six-for-a-quarter tickets, excepting in special hours. The regular fare will be five cents, or five tickets for a quarter. School children's tickets will remain the same. It is provided that this arrangement shall last for one year after the end of the war.

Use All Steam Plants

At a recent meeting of the Guelph, Ont., board of light and heat commissioners it was decided that arrangements be made immediately with all power users who have steam plants not in use to start them at once and use to the fullest extent. If this does not furnish the required load the commissioners have further decided that all power users who have no war contracts will have to discontinue the use of power. Electric heaters must not be used from 7 a.m. to 6 p.m. excepting at the noon hour, Saturday afternoons, Sundays and holidays. The street railway is also affected by the power shortage, being only able to run in restricted hours.

Trade Publications

C. G. E. Publications—Bulletin 47135A, standard unit alternating current switchboard panels for general use in isolated and small plants, 1150 and 2300 volts; Bulletin 47050A, standard unit direct current small plant switchboard panels for two-wire general power and lighting service; Pamphlet No. 622, electric heaters for the home, office and factory; two leaflets, describing "Holophane" reflectors and fittings and "Holophane" Realites and special units; Bulletin 40017, small direct-current generators, type ML; Bulletin 46500, C. G. E. indicating flow meter, type FS-2 for steam, FW-2 for water and FA-2 for air; Leaflet 68413, CR 2940 push button stations.

Electrical Blue Book—8th edition, 1918; International Trade Press, Inc., Chicago, publishers; 274 pages, 9 x 12 inches, cloth binding, illustrated, price $2.00. The book is composed of three principal parts. The first comprises some 150 pages of catalog exhibits of approved electrical fittings and appliances as produced by the leading electrical manufacturers; all of these pages are well illustrated. In the second part is given an outline of the Underwriters' Laboratories Inspection Service, with a list of the branch offices and stations and followed by a complete list of inspected appliances and material. The third part consists of the complete National Electrical Code, 1918 edition—the first appearance of this latest code with all the revisions indicated. There is also printed a list of the members of the Electrical Supply Jobbers' Association; a general directory of electrical associations and a complete buyers' guide of electrical apparatus and material.

Electric Iron, Limited, Orillia, Ont., have been granted a Dominion charter.

Current Notes

The Nitro-Daylight Lamp Company have moved from 46 Queen Street East, Toronto, to 12 Queen Street East.

A by-law authorizing an expenditure of $10,000 to bring Hydro power into the township of Markham, as far as Unionville, has passed its third reading in the township council.

The British Columbia Electric Railway Company have announced that all returned soldiers minus an arm or leg are entitled to free transportation on any of their city lines.

The Swedish General Electric Company have moved from 11 Dundas street to larger quarters at 109 Duke street, formerly occupied by the Lancashire Dynamo and Motor Company.

The Arcwell Corporation of Canada, Limited, has been granted letters patent and will carry on a general electrical business. The capital stock is given as $1,000,000 and the head office, Toronto.

The Canadian Import Sales Company have opened offices in the Foy Building, 34 Front Street West, under the management of Mr. C. R. Connors. They carry a complete line of flashlight cases and bulbs as well as various other lines of electrical specialties.

Electrics, Limited, have opened offices at 22 St. John street, Montreal. The Company have secured a federal charter, and have elected the following officers: Mr. Stephen H. Wiggett, president; Mr. Andrew C. Hersey, vice-president, and Mr. G. H. Rainville, managing director. The firm are wholesale distributors for Westinghouse "Mazda" lamps, and also for motors, generators and other electrical equipment manufactured by the Westinghouse Company. Both Mr. Hersey and Mr. Rainville are returned officers, who have served overseas for three years each.

Personal

Mr. H. E. Randall has resigned his position as purchasing agent of the Shawinigan Water and Power Co., to take up an appointment with the Ludlum Electric Furnace Corporation, New York. Unfortunately he was taken ill with influenza when about to leave Montreal and had to be removed to a hospital.

Obituary

Mr. Michael Mackay, a well-known telegrapher and formerly manager of the C.P.R. system at Quebec City, died in Montreal recently.

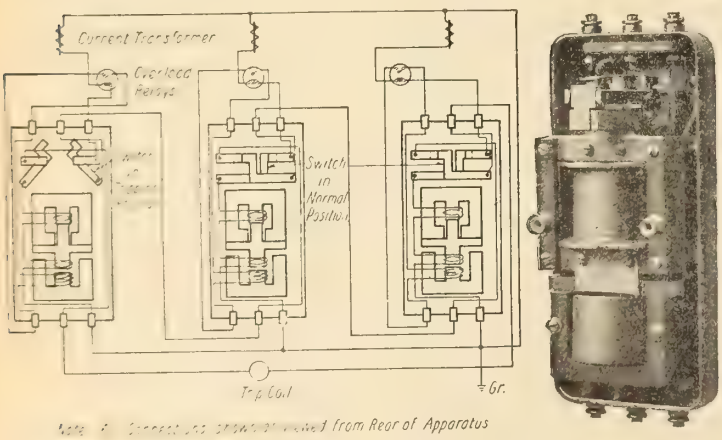
Mr. Frederick G. Wurster, one of Galt's most prominent business men and manager of the local office of the Bell Telephone Company, died recently.

Mr. Ross Bodell, commercial supervisor of the G.N.W. Telegraph Company, Toronto, died a few days ago, a victim of influenza.

Private W. C. Gardner, former traffic chief of the Eastern division of the Bell Telephone Company, Montreal, died in the Royal Herbert Hospital, Woolwich, England, from pneumonia. He joined a draft of the Canadian army service corps in June last and contracted a chill on the voyage to England.

Mr. Frederick J. Dunn, contract agent of the lighting department of the Westmount Corporation, died in the Royal Victoria Hospital on October 11 from pneumonia, following influenza, aged 50. Prior to his appointment with the Westmount Corporation, Mr. Dunn was employed with the Montreal Light, Heat, and Power Co., going to that concern when the Royal Electric Co. was merged with the Montreal Gas Co.

Am I the Man From Glencoe?



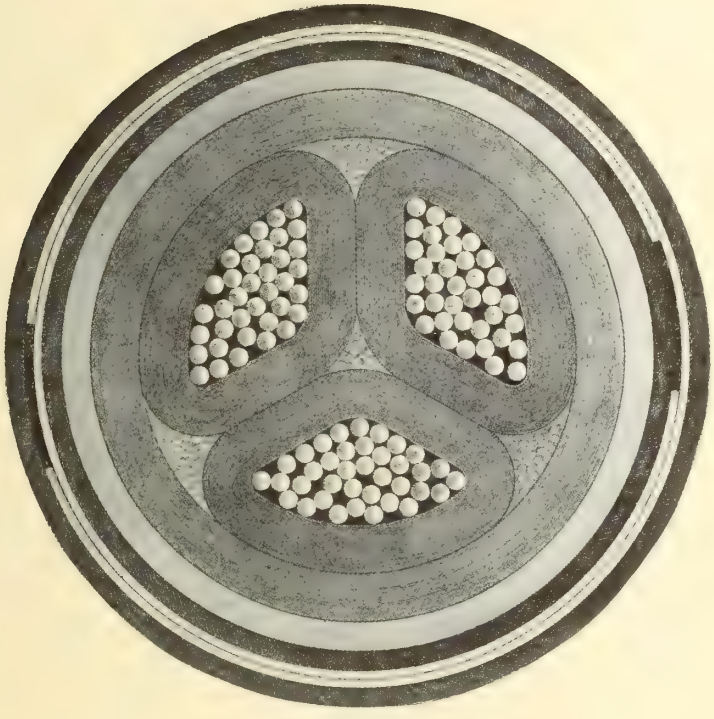
A Glencoe man was asked recently to contribute to one of the war funds, and replied that he "felt he had done enough." A well-known writer in the Chicago Tribune has this to say about the gentleman:

In other words, so far as he is concerned, the war is over and done with. Men whose time is more valuable than the money they give or raise are devoting their entire days to the country's service; but the Glencoe man feels that he has done enough. Women discharge their servants, do their own housework, and labor in Red Cross and other war shops; but the Glencoe man feels that he has done enough. Soldiers, discharged from hospitals in France, feel that they still have something to give, and return to the trenches, but the Glencoe man feels that he has done enough. Mothers, with aching hearts, are sending their sons away to an unknown fate; but the Glencoe man feels that he has done enough. It must be pleasant to be so circumstanced mentally. Few of us are able to forget that the war is still going on.

But passing the hat isn't the best thing we do. We are not diplomatic. We have a healthy and perfectly good-natured contempt for a man who can give and won't give, and we haven't any objection to his knowing it. We don't owe him anything—not even, in these days, politeness.

Transfer Relay

Protective relays that operate by closing a separate direct-current tripping circuit which in turn trips the circuit breaker, have proved more serviceable than "shunt-trip" relays and have come into very general use. In some cases, however, a separate direct-current tripping circuit is not available and other means must be sought. The use of "transfer" relays is the best solution so far obtained, for they energize the trip coil off the circuit-breaker through current transformers. While designed particularly for use with the Westinghouse types CO and CR relays, the type BT relay can be applied to any make of circuit-closing relay of similar characteristics. The breaker operates solely through the current transformer and the relays. When there is no fault on the line, the trip coil of the breaker is mechanically



and electrically isolated from the circuit, avoiding possibility of tripping due to imperfection in the relay contacts ordinarily shunting the trip coil. The relay contains two series coils, an upper or operating coil and a lower or holding coil (see diagram of connections). The holding coil holds down the armature core, until a third coil, wound on the same magnetic circuit and known as the releasing coil, is short-circuited by the protective relay. The releasing coil acts as the secondary of a transformer and when short-circuited a current flows through it, demagnetising the core. The holding coil, therefore, allows the operating coil to raise the core which operates the transfer switch, thus closing the trip coil circuit. The transfer switch and other current carrying parts of the relay are designed to carry 5 amperes continuously, but during times of short circuit the switch may be called on to handle as much as 100 or 200 amperes. A current transformer may be selected of sufficient capacity to operate the protective relay, the transfer relay and the trip coil. Low-ratio bushing-type current transformers sometimes used on high-voltage circuit-breakers are not suitable. Only one trip coil is required for use on a polyphase circuit, but if the breaker is equipped with as many trip coils as there are relays, it is advisable to connect each trip coil to its corresponding relay.

Trade and Reconstruction in Germany

In the last issue of the British Board of Trade Journal some account is given of the preparations now being made in Germany to meet the special conditions which will obtain on the cessation of hostilities. It is interesting to note that Economic Boards are to be established. It is not intended to exclude private trade, but to set up these boards and give the industries a form of self-government. It is proposed more particularly that these boards should exercise control over the distribution of the foreign exchange and of tonnage. With regard to the latter, the Tonnage Distribution Office of the German shipping industry will decide questions of a technical nature, and the preference that is to be given to the various goods in shipping. Owing to the probability of the scarcity of tonnage, the German Government has arranged for a subsidy to be paid to the shipping industry in compensation for their war losses, and there are to be stringent regulations so that shipping is retained and is used, firstly, for the transport of absolutely necessary imports, such as food and raw materials; and secondly, for requirements that are purely German and not foreign. The Economic Board for the textile trades will regulate the distribution of certain kinds of wool and fibres to the cotton spinners as substitutes for cotton. In this connection it may be noted that, out of 1,700 spinning and weaving factories in Germany, only 70 large ones are now working; in the silk trade, out of 45,000 looms, only 2,500 are at work; in the oil industry only 15 ont of 720 firms are still active; while in the boot and shoe trade half the firms have closed down. The most important to note, however, is that the German Government is quite alive to the problems that will have to be faced in reconstruction, and in this country we shall do well to see to it that our plans are fully prepared and that the Germans do not make use of our methods before we put them into execution ourselves.—Electrician.

Electrical Books—Special Prices

The following Books are Offered Subject to Previous Sale:

A Handbook on the Steam Engine, by Herman Haeder. Published in 1914 by Crosby, Lockwood & Son. 522 pages, illustrated. Price $3.00.

A Laboratory Manual of Alternating Currents, by John H. Morecroft, E.C. Published in 1912 by Renouf Publishing Company. 248 pages, illustrated. Price $2.00.

Alternating Currents—Examples for Students and Engineers, by Prof. F. E. Austin. Second edition, Vol. I. Published in 1916. 223 pages, illustrated. Price $2.40.

Baudot Printing Telegraph System, by H. W. Pendry. Published in 1913 by Whittaker & Company. 144 pages, illustrated. Price $1.00.

"Central Stations," by Terrell Croft, 1st edition published in 1917, by McGraw-Hill Book Co., Ins. 332 pages, illustrated. Price $2.50.

Direct-Acting Steam Pumps, by Frank F. Nickel. Published in 1915 by McGraw-Hill Book Company. 258 pages, illustrated. Price $3.00.

Direct Current Machinery, Theory and Operation of, by Cyril M. Jansky, B.S., B.A., 1st edition, just published by McGraw-Hill Co., Inc. 285 pages, illustrated. Price $2.50.

Dynamo-Electric Machinery, by Francis B. Crocker, E. M., Ph.D. Published in 1908 by American School of Correspondence. 236 pages, illustrated. Price $1.00.

Electric Arcs, by Clement D. Child, Ph.D. Published in 1913 by D. Van Nostrand Company. 194 pages, illustrated. Price $2.00.

Electric Car Maintenance, by Walter Jackson. Published in 1914 by McGraw-Hill Book Company. 274 pages, illustrated. Price $2.00.

Electric Cooking, Heating and Cleaning, by Maud Lancaster. Published in 1914 by D. Van Nostrand Company. 330 pages, illustrated. Price $1.50.

Electrical Machinery—Principles, Operation and Management, by Terrell Croft. Just published by the McGraw-Hill Book Co. 318 pages, illustrated. Price $2.00.

Electrical Meters, by Cyril M. Jansky, B.S., B.A. Second Edition, just published by McGraw-Hill Book Company. 416 pages, illustrated. Price $3.00.

Electric Railway, by A. Morris Buck, M. E. Published in 1915 by McGraw-Hill Book Company, Inc. 390 pages, illustrated. Price $3.00.

Electric Railway Engineering, by C. Francis Harding, E. E. Second Edition. Published in 1916 by McGraw-Hill Book Company. 416 pages, illustrated. Price $3.00.

"Electric Traction," a treatise on the application of electric power to tramways and railways, by A. T. Dover. Published in 1917 by Whittaker & Co. 661 pages with 518 illustrations and five folding plates. Price $6.00.

Electrical Injuries, by C. A. Lauffer, M.D., published in 1912 by John Wiley & Sons. 77 pages. Price 50 cents.

Electro-Dynamics, by Charles Ashley Carus-Wilson. Published in 1898 by Longmans, Green & Company. 298 pages. Price 50c.

Elementary Principles of Illumination and Artificial Lighting, by Arthur Blok, A.M.I.E.E. Published in 1914 by Scott, Greenwood & Son. 235 pages, illustrated. Price $1.00.

Elementary Graphic Statics, by John T. Wight. Published in 1913 by Whittaker & Company. 226 pages, illustrated. Price 75c.

Elementary Magnetism and Electricity, by Cyril M. Jansky, B. S. Published in 1914 by McGraw-Hill Book Company. 212 pages, illustrated. Price $1.50.

Engineers' Manual, by Ralph G. Hudson. Just published by John Wiley & Sons. 315 pages, illustrated. Price $2.00.

Examples in Alternating-Currents, (Vol. 1), by F. E. Austin, B.S. Published in 1915. 223 pages, illustrated. Price $2.00.

Examples in "Battery Engineering," by Professor F. E. Austin, E.E. Just published. 90 pages, illustrated. Price $1.25.

Examples in Magnetism for Students of Physics and Engineering, by Prof. F. E. Austin, B. S. Published in 1916. Price $1.00.

First Aid in Case of Electrical Shock, by Dr. John Woodman. Published in 1908 by the New York Edison Company. Illustrated. Price 50 cents.

Handbook of Machine Shop Electricity, by C. E. Clewell. Published in 1916 by McGraw-Hill Book Company. 461 pages, illustrated. Price $3.00.

How to Make High-Pressure Transformers, by Professor F. E. Austin. Second edition, just published. 48 pages, illustrated, price 65c.

How to Sell Electrical Labor-saving Appliances." Recently published by McGraw-Hill Book Co. 115 pages, illustrated. Price $1.00.

"Practical Electricity," by Terrell Croft. First edition. Just published by McGraw-Hill Book Co. 646 pages, illustrated. Price $2.50.

Practical Electric Illumination, by Terrell Croft, First edition, published by the McGraw-Hill Book Co. 225 pages, illustrated. Price $2.00.

Principles of Direct Current Machines, by Alexander S. Langsdorf, M. M. E. Published in 1915 by McGraw-Hill Book Company. 404 pages, illustrated. Price $3.00.

Principles of Alternating Current Machinery, by Ralph R. Lawrence. Published in 1916 by McGraw-Hill Book Company. 614 pages, illustrated. Price $4.50.

Principles of Electrical Design—D.C. and A.C. Generators, by Alfred Still. Published in 1916 by McGraw-Hill Book Co. 365 pages, illustrated. Price $3.00.

Radiodynamics—The Wireless Control of Torpedoes and Other Mechanisms, by B. F. Miessner. Published in 1916 by D. Van Nostrand Company. 206 pages, 112 illustrations. Price $2.00.

"Radio Communication, Theory and Methods, with an appendix on Transmission over Wires," by John Mills. First edition, just published by McGraw-Hill Book Co., Inc. 205 pages illustrated. Price $1.75.

Radiation, Light and Illumination, by Steinmetz. Published in 1909 by McGraw-Hill Book Company. 304 pages, illustrated. Price $2.50.

Standard Wiring, 1918 Edition, 24th Year. The National Authority on Wiring and Construction. By H. C. Cushing, Jr. Leather cover, pocket size. Price $1.50 postpaid.

Steam Power Plants—Their Design and Construction, by Henry C. Meyer. Published by McGraw-Hill Book Company in 1903. 158 pages, illustrated. Price 50c.

Steam Turbines, by Robert M. Neilson. Published in 1903 by Longmans, Green & Company. 294 pages, illustrated. Price $1.00.

Steam Turbines, by Kennedy. Published in 1910 by Whittaker & Company. 100 pages, illustrated. Price $1.00.

Telegraph Practice, a Study of Comparative Method, by John Lee, M.A. Just published, by Longmans-Green & Co. 102 pages. Price $1.00.

Telegraphy—A Detailed Exposition of the Telegraph System of the British Post Office, by T. E. Herbert, A.M. Inst. E.E. Third edition. Published in 1916 by Whittaker & Company. 985 pages, 630 illustrations. Price $2.00.

Telegraphy, by Sir W. H. Preece, K.C.B., and Sir J. Sivewright, M.A. Published in 1905 by Longmans, Green & Company. 504 pages. Price $1.00.

Test Methods of Steam Power Plants—A Reference Book for the Use of Power Station Engineers, Superintendents and Chemists, by Edward H. Tenney, B.A. M.E. Published in 1915 by D. Van Nostrand Company. 224 pages, 85 illustrations. Price $2.50.

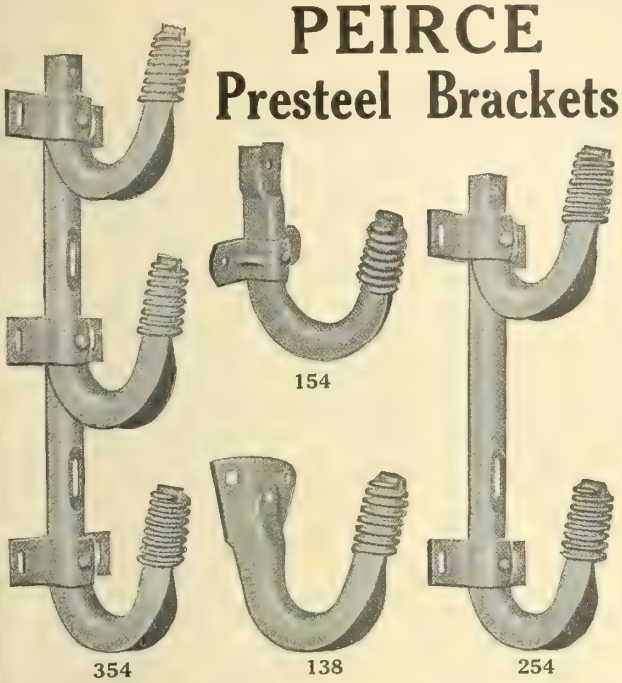
The Electrical Contractor; Principles of Cost-Keeping and Estimating, by Louis W. Moxey, Jr. Published in 1916 by McGraw-Hill Book Company. 86 pages, illustrated. Price $1.50.

The Dynamo (2 volumes), by Hawkins & Wallis. Published in 1909 by Whittaker & Company. Price $4.00.

The Lighting Art, Its Practice and Possibilities, by M. Luckiesh. First edition, just published by McGraw-Hill Book Co., Inc. 229 pages, illustrated. Price $2.50.

The School of Practical Electricity (Electrician's Course in 2 volumes). Volume 1. Published by Electroforce Publishing Company, Milwaukee, Wis. 410 pages, illustrated. Price $4.50.

The Practical Railway Spiral, by L. C. Jordan, C.E. Published in 1913 by Van Nostrand Company. 155 pages. Price 75c.



Transmission Line Crossings, by Frank F. Fowle. Published in 1909 by D. Van Nostrand Company. 69 pages, illustrated. Price $1.00.

Treatise on Thermodynamics, by Dr. Max Planck. Published in 1903. 272 pages. Price $1.00.

Wray's Manual of Car Lighting. Published in 1915 by Wray Publishing Company. 340 pages, illustrated. Price $1.50.

Steam Engines and Alternators

FOR IMMEDIATE SALE

ALL OF CANADIAN MANUFACTURE

1 500 h.p. vertical cross compound, 4 valve engine with shaft governors, cylinders, 18 and 24 x 24 in., 150 r.p.m., with one 325 k.w., 3 phase 60 cycle, 2300 volt alternator direct coupled; also belted exciter.

1 900 h.p. vertical cross compound, 4 valve engine with shaft governor, cylinders, 20 and 38 x 24 in., 150 r.p.m., with one 600 k.w., 3 phase 60 cycle, 2300 volt alternator direct coupled; also belted exciter.

All of them have been operated at 135 pounds steam pressure and about 25 in. vacuum. All in good order; some of them have been run recently.

Purchaser to make his own inspection, to have access to all available records, and to remove equipment at his own expense.

These engines ought to be sold entire, and would be an advantageous purchase for any establishment where reciprocating engine power can be economically employed, especially where exhaust steam has commercial value, as it frequently has in isolated power plants, or in central stations supplying a steam heating service.

Correspondence is desired with parties who may have immediate use for any or all of these engines or parts thereof. Prices on application, subject to prior sale.

WINNIPEG ELECTRIC RAILWAY CO.,

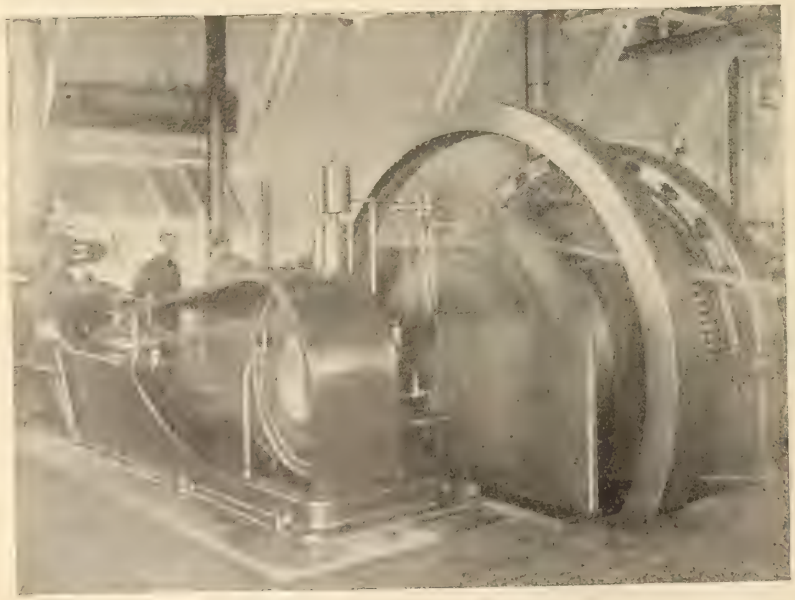
You Know the Noise!



caused by commutators sparking and flashing—the result of undue friction between brushes. This trouble can be cured by fitting your machines with

No-Spark Carbon Brushes

They run smooth, do away with the continual cleaning, replacing and resetting because these brushes are frictionless and self-lubricating. Try "NO SPARK" Brushes. Other engineers are enthusiastic over them. Why not you?

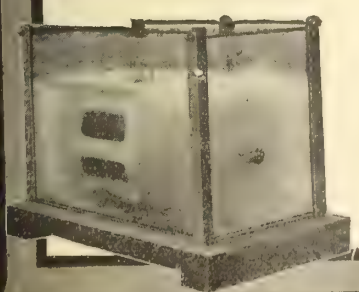
LINCOLN MOTORS

Lincoln Arc Welders

SAVE 50%

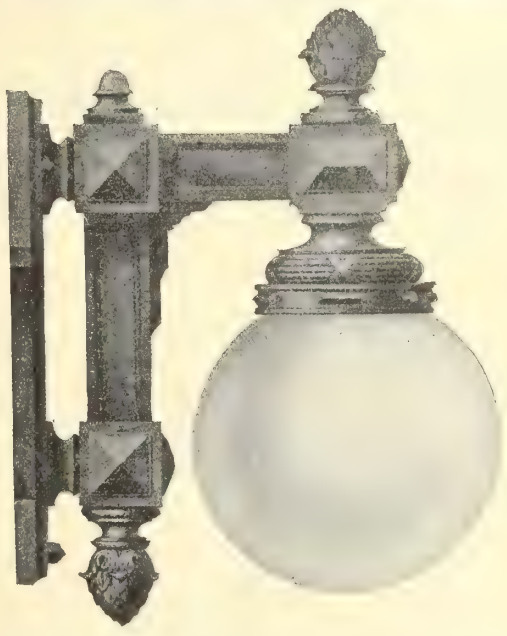
You can save 50% — very often more—by doing your boiler plate work with a Lincoln Arc Welder instead of rivetting it.



Lincoln-welded joints are 100% strong — rivetted joints are no stronger than the rivets themselves.

The Lincoln Arc Welder avoids awkward overlapping on corners, thus saving time.

Its heat is greater, more concentrated, and more readily controlled than that of any gas or other welding system, and the current is all usefully employed—there are no "ballast resistances" to waste 50% to 80% of the power taken.



It has been adopted by boiler shops, structural steel works, street car and railroad companies as being the most practical solution of the present labor shortage.

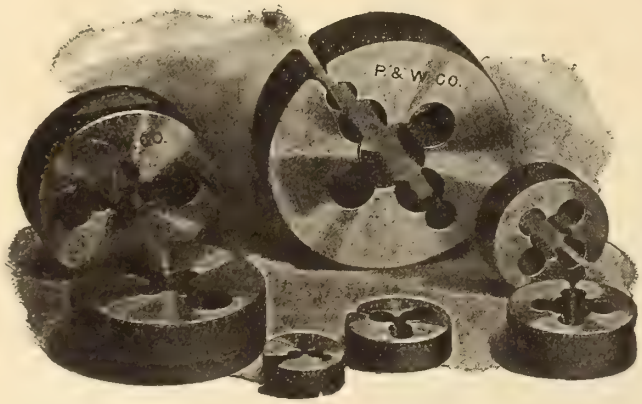
GROWTH—

Day after day, week after week, month after month, for the five years that Economy Fuses have been on the market, the sales have maintained a constant growth—not alone in volume, but also in percentage of increase. This is because

ECONOMY Renewable FUSES



are absolutely accurate in operation and cut annual fuse maintenance costs 80%. An inexpensive little "Drop Out" Renewal Link restores a blown Economy Fuse to its original efficiency.

The Safest and Best Way

to control your lighting is with

Krantz Safety Panel Board

Can be operated by a child in perfect safety, all live parts are protected with lock and key.

Krantz Panel Boards are easy to install and present a neat appearance, they represent the latest achievement in panel board construction and design.

See that you specify "Krantz" on all your orders.

ESTABLISHED 1849
BRADSTREET'S
Offices Throughout the Civilized World.
Executive Office:
Nos. 346 and 348 Broadway, New York City, U. S. A.

THE BRADSTREET COMPANY gathers information that reflects the financial condition and the controlling circumstances of every seeker of mercantile credit. Its business may be defined as of the merchants, by the merchants, for the merchants. In procuring, verifying and promulgating information no effort is spared, and no reasonable expense considered too great, that the results may justify its claim as an authority on all matters affecting commercial affairs and mercantile credit. Its offices and connections have been steadily extended, and it furnishes information concerning mercantile persons throughout the civilized world.

Subscriptions are based on the service furnished and are available only by reputable wholesale jobbing and manufacturing concerns, and by responsible and worthy financial, fiduciary and business corporations. Specific terms may be obtained by addressing the company at any of its offices. Correspondence invited.

THE BRADSTREET COMPANY
Offices in Canada: Halifax, N.S.; Hamilton, Ont.; London, Ont.; Montreal, Que.; Ottawa, Ont.; Quebec, Que.; St. John, N.B.; Toronto, Ont.; Vancouver, B.C.; Victoria, B.C.; Winnipeg, Man.; Calgary, Alta.; Edmonton, Alta.

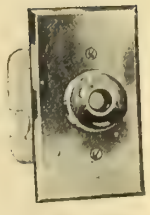
HUBBELL

STANDARD

Plugs and Receptacles

No. 6915



No. 5406

SUPERIORITY brings its own reward. It may take years, but it comes. Years ago Hubbell Plugs and Receptacles went through the try-out period—the struggle for recognition. They were an innovation—an independent and distinctive creation. They pioneered the principle of **Interchangeable Connections**—made possible a greater and safer electrical service. For years they have been recognized as standard. Superiority brings its own reward.

LIGHT INTENSITY

with a minimum of Power

is obtained with the

Pittsburgh Show Window Reflectors

They will increase the light 400 per cent. to 500 per cent. This has been established by scientific test.

Illustration shows "Pittsburgh" Reflector No. 100 for 100 or 150 Watt Lamp. Dimensions: Height, 5½ inches; width, 8 inches; Holder, 2 ins. Form "O"

It will be to your advantage to learn more about the efficiency of these Reflectors. Write to-day for illustrations of the different types of reflectors for show windows and indirect lighting.

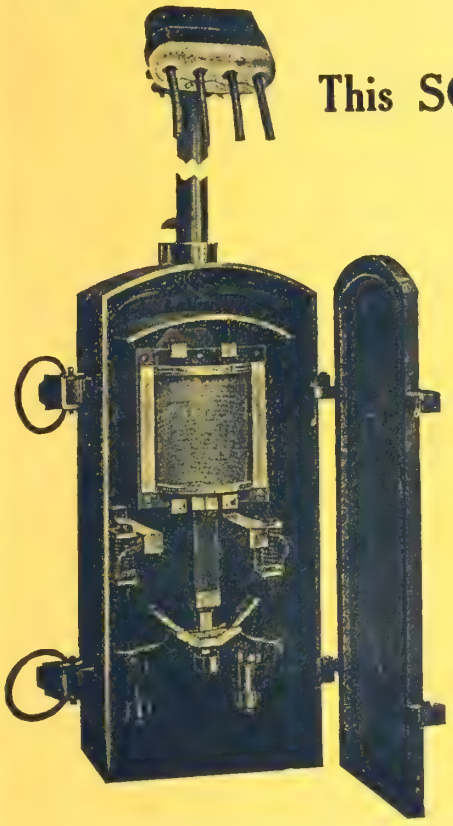
Electric Service Transformers

Westinghouse Oil-Insulated, Self-Cooling Electric Furnace Transformer

All Westinghouse Electric Furnace Transformers are built to withstand the heavy overloads and other unusual requirements, demanded in electric furnace service.



Special attention has been given to the interlacing of the coils, and bracing of the windings.

Oil-insulated transformers are supplied in either self-cooled or water-cooled types, in all capacities and voltages, and for frequencies of 25 to 60 cycles; single, two or three phase.

Leaflet No. 3923 describes Westinghouse Equipment for Electric Furnaces.

This SOLENOID SWITCH has been adopted by the Hydro Electric Commission

They use it for

STREET LIGHTING

Now the fact that it is used by the Hydro-Electric Commission is proof that it is all we claim for it. It certainly is not an experiment, by the fact that it is giving efficient service in many towns throughout Ontario, as well as the other provinces.

No springs, swivels or other complicated mechanisms to give trouble. They close magnetically and are opened by gravity assisted by the tension of the laminated copper contact. All arcing is taken up on the carbons.

Increase the efficiency of your system and decrease the cost of installation by using our Type 17 H.E.P. Solenoid Switches, which are suitable for any frequency on multiple circuit or D.C. Series circuit.

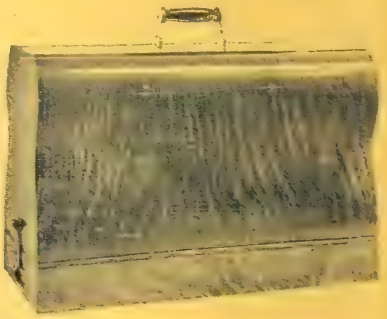
Why Not Order a Good Supply of

Northern Electric

Portable Sewing Machines NOW?



Remember the greatest need for sewing by electricity is now, when the women of Canada are so extensively engaged in doing their own as well as a large amount of patriotic sewing work at home.

The Northern Electric Sewing Machine eliminates the tiresome, back-aching treadle work of the old method, and enables the operator to do twice as much sewing without effort.

The Northern Electric Sewing Machines are of the highest grade in design and workmanship, and carry a guarantee of complete satisfaction in every way.

Several different types are obtainable in both portable and stand style machines. You can secure either vibrating shuttle or bobbin type.

LITTLE WORDS WITH BIG MEANING

Quality

According to "Webster," Quality is "an excellence of character; natural superiority."

Service

Webster's definition of "Service" is; "The performance of labor for the benefit of another."

We use these words advisedly—fully understanding their definitions—and realizing the obligation we place upon ourselves by their continued use in connection with our products of Iron and Steel, and our attitude to the people we serve.

The "FRANKLIN"

Positive Lock

as incorporated in the

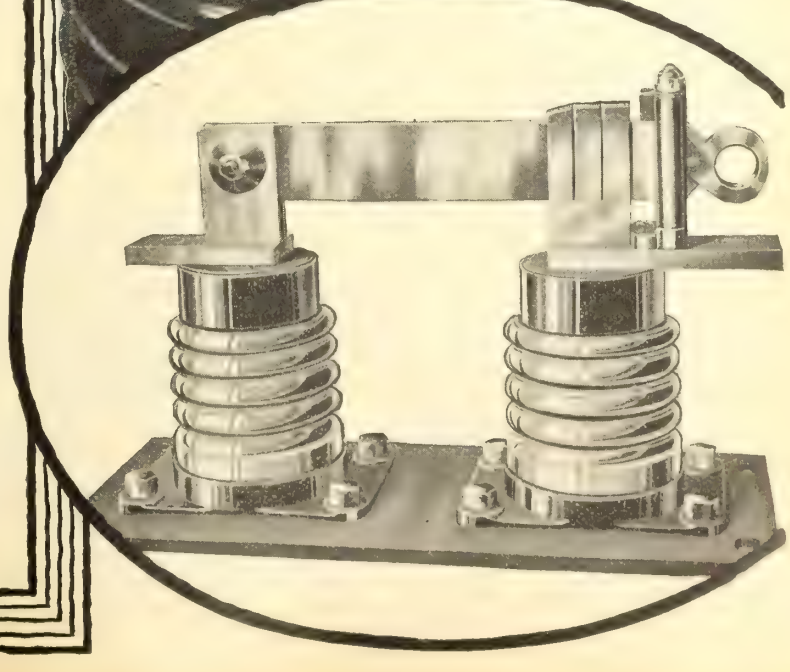
FRANKLIN

Disconnecting Switch

THIS phantom view will show you why the "FRANKLIN" Switch Lock is superior in locking effectiveness, in convenience of operation, and in durability to previous devices designed for the same purpose.

The switch-blade is held closed by two rugged brass jaws which form a closed bridge above it. The jaws cannot be forced open by electrical expulsion strains because they open only in a direction OPPOSITE to that of the resultant electrical forces.

The jaw-castings are rugged and rigid. There is no strain whatever upon the springs except momentarily, as the switch-blade passes in or out.



A single pull, with any kind of hook, opens the switch. It causes the cams fixed to the pull-ring to rotate against the lugs projecting from the jaw castings. As the jaws are thus rotated against the springs, the bridge above the blade opens and permits the blade to pass out

The bevelled tops of the jaws permit the blade to pass in easily, so that a single push of a hook will close the switch. When the blade is home, the springs return the jaws with a vigorous, unmistakable snap.

Let us send you Bulletin No. 1250, which describes "FRANKLIN" Disconnecting Switches with "FRANKLIN" Positive Locks. State service and voltage when you write.

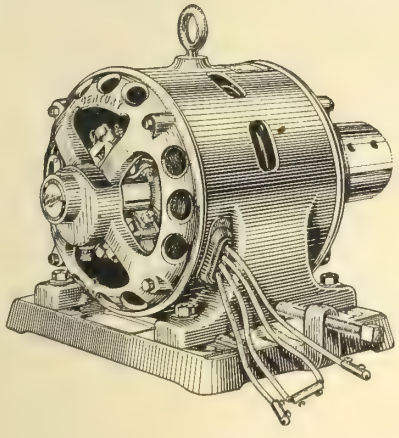
Absorbs the Shock

Our special C. & H. Poly-Phase Meter is safe because it is fitted with new double terminal blocks that absorb the shock and reduce the danger of accident resulting from overloaded wires and from surge conditions during lightning storms.

This meter also has more inside room for the connections, and the three or four lines are carried straight through the meter from the left to right. In every respect this C. & H. Poly-Phase is a Safety Meter, and is undoubtedly the one to select for Installation on Long Distance Transmission.



C & H Poly-Phase The Safety Meter

The Company's guarantee goes with every instrument. The new Poly-Phase is as near perfect as it is possible for a meter to be.

THE "TYPE S" PORTABLE WHEATSTONE BRIDGE

Useful in the Shop and Laboratory for the Measurement of Resistance. Adapted for Fault Locations in Telegraph and Telephone Lines and Cables.

The Type S Bridge is a thoroughly practical instrument for shop and field use. Being complete in every detail it is ready at all times for immediate use. It is easily portable, its weight being but 8 pounds. The precision of adjustment of its coils (Rheostat 1/10 per cent., Ratio 1/20 per cent.) insures accurate measurements. The galvanometer, the weakest element of such an instrument, is unusually rugged. It is a separate element and may be removed for examination or repair by taking out two screws. The battery is of the ordinary "flash light" type, and renewals may be procured practically everywhere. The price is $66.25 net, f.o.b. Philadelphia, boxed for shipment.

Bulletin No. 530 describes this instrument.

Kraft Cord "Braiduct"

Made in Canada under Canadian Patent No. 147,057

This cut is reproduced from an actual photograph, and illustrates the behavior of the material in this rigid test—perfect flexibility. We cut the ends to show plainly the superior construction—note the high grade Canvas Duck Lining and the KRAFT CORD winding. This KRAFT CORD is made to our own specifications and is fire-proofed, which is entirely new.

KRAFT CORD "BRAIDUCT" is in a class by itself—superior to any imported conduit—is absolutely the last word in flexible non-metallic conduit construction.

We are now making our own insulating compounds, consequently every lot will be uniform in flexibility, and every foot is fished at the factory.

KRAFT CORD "BRAIDUCT" is easy to instal—easy to cut—easy to secure, as it is made in our own country, and easy to buy, as our price is right.

KRAFT CORD "BRAIDUCT" is packed in heavy fibre boxes, each box containing four coils (1,000 ft.), insuring product against damage in transit.

KRAFT CORD "BRAIDUCT" is regularly inspected and labelled by the **Underwriters' Laboratory** under the direction of the **National Board of Fire Underwriters** and every coil carries their label.

We will be glad to send you a sample.

O-B PRODUCTS
Quality First

O-B Type N Lock Hanger

O-B LOCK HANGERS FOR TRUE LINE ECONOMY

O-B Lock hangers do everything the regular hanger does and then go farther. They make every ear seat solidly.

The illustration shows their construction. The ear is turned up until it touches the metal bearing surface at the bottom of the hanger. Then it is tightened still further until it aligns with wire, pulling the stud down in opposition to the spring washer.

Since there is a tight joint between ear and hanger there is no see-saw action to destroy the thread.

For the same reason no moisture gets in to start corrosion. When the ear is worn it may be removed easily, without scrapping, too,

There are various types of O-B hangers listed in Catalog No. 16 and Supplement No. 1. Either or both books sent free on request.

Service Which Wins The Electrician's Support for the Motor Distributor

Where R & M Motors are in service the plant electrician is usually an active booster for the distributor who supplied the motors. Their unfailing reliability conserves his time and gives him opportunity for constructive planning—the kind which shows results that are reflected in his pay check.

An occasional cleaning and oiling of the motors and he is free for other work.

While the plant electrician is not often the man who signs the order when motors are purchased, he is the man who knows best how the motors in the plant are performing. Consequently his opinions have a lot of weight with the man who does sign the order.

You'll find it pays well to cultivate the electrician's good will toward your motor business. And you'll find R & M Motor reliability a most effective means of winning his support.

For individual room heating

Your great economy problem this Fall and Winter will be the low cost of heating your home. Whether your present heating system is the old-fashioned coal heater or the modern hot water system it can be regulated to conserve fuel. But in doing this, all the rooms are not being properly heated.

The Hughes Electric Air Heater is an auxiliary heater which acts as a fill-in and makes this fuel conservation possible. The heat is instantly regulated to the requirement which makes it ideal for individual room heating. Portable, and can be moved from room to room—quickly warming it to a comfortable temperature.

It's a wonderful convenience these cold mornings, giving heat when you want it and where you want it. Especially in the Spring and Fall or on an extremely cold day when there is just a little more heat needed to make it comfortable. At the turn of a switch you have the necessary heat without the noxious fumes that wither plants, or the fire hazard, ashes and smoke with the worry of keeping things clean. When not in use can be stored in a small space. Built with steel body, cast iron base—will last for years. Finished in black enamel and nickel trimming.

Phone your electrical dealer or contractor regarding the necessary wiring

Immediate Need For Money To Keep Street Railways Running

The full text of the report to the Minister of Labor by Chief Justice Mathers, Isaac Pitblado, K.C., and R. C. Ward, on the conditions obtaining in Winnipeg between the Winnipeg Electric Railway Company and its employees, has just been made public. The condition in Winnipeg has been aggravated in the past by the competition of jitneys, but this was recently eliminated. However, no dividends have been paid by the company since 1915, and when a recent demand was made by the men for increased wages, the company was met with the alternative of practical bankruptcy or the necessity of increasing the revenue through an increased fare. The report referred to above stated that to accede to the demands of the employees would be putting the company into immediate insolvency and the recommendation of the committee includes both that the wages of the men shall be increased and also that the fares, as already noted in previous issues of the Electrical News, shall be brought into conformity with the greatly increased costs of maintenance and operation of the system. The new wage award which was put into effect on October 1, is as follows: for the first six months, 39 cents per hour; for the second six months, 41 cents per hour; for the second year, 44 cents per hour; for the third and succeeding years, 47 cents per hour. The committee took the stand that the request of the company for increase in fares was not a matter of the history of the relations between the local street railway and the municipality, nor did it rest upon any right to a dividend upon capital invested in the enterprise. The increase must be given, however, because of immediate pressure for money necessary to keep the street railway running so that they may meet the local and national demands for their service. In justice the public should pay an adequate war compensation for a service that cannot be rendered except at war prices.

These are conditions which obtain practically all over the continent. They have been recognized as just and right in a number of cities. In other cases, however, there is still no evidence that the companies operating railway systems are to be shown any measure of justice. Whatever may be said of Germany, it apparently cannot be said of all Canadian municipalities that they have "won that victory over themselves which teaches that might is not right."

Timely Organization of Toronto's Illuminating Engineers

Shortly before the outbreak of war, there was a movement among engineers specially interested in illuminating matters, to form an association for the study and discussion of problems connected with better lighting of our homes, offices and factories, but, unfortunately, some of the moving spirits were called to active service and the matter was temporarily held in abeyance. With evidence of the struggle drawing to a close, however, interest has been again revived and a few weeks ago, a number of Toronto members of the Illuminating Engineering Society of the United States, met to discuss the advisability of further organization. A meeting was held in Mr. W. P. Dobson's office, Strachan Avenue Terminal Station, and it was decided that an endeavor would be made to hold meetings monthly, or even more frequently, for the reading and discussion of scientific and practical papers.

The first meeting of this nature was held on Tuesday evening, November 5, with Mr. H. D. Burnett in the chair, and was well attended. A semi-technical paper was read by Mr. Geo. G. Cousins, a member of the research laboratory of the Hydro-electric Power Commission of Ontario, on the subject of "Photometry." Mr. Cousins' paper consisted of an historical review of the development of photometry, a description of the various photometers in use in the Hydro laboratories and some interesting figures regarding results obtained in tests on lamps and reflectors of various kinds. Extracts of the paper are printed elsewhere in this issue.

It would seem that Toronto illuminating engineers have chosen an opportune moment to initiate concerted action along the lines of a greater knowledge of the subject of correct lighting. It is to be expected, now that the feverish haste associated with the production of war materials is a thing of the past, that we, as a nation, will have more time to consider the essentials of quality production. The contest of the next few years among the nations of the world will be won by the nation that can produce goods of the highest quality. It follows that workers, in general, must operate under conditions of the most favorable possible nature—and nothing adds more to the efficiency of a workman than proper lighting. This is equally true whether we consider the lighting of the factory or office in which he works, or of the home in which he passes his hours of recreation. Canada, situated as she is, in the more northerly latitude of the hemisphere, spends more hours than most countries surrounded by artificial illumination. This in itself constitutes an all-sufficient reason why the greatest possible care should be taken in our lighting installations. In proportion as our lighting is inadequate and improperly installed, the products of our hands and minds will fall short of the standard required to compete in the markets of the world.

Another New Industry for B.C.

The plant now being erected on the North Arm of Burrard Inlet by the American Nitrogen Products Company, will be the first electro-chemical factory in Western Canada. It marks one more forward step in the industrial advance of British Columbia. Other similar concerns should follow when it becomes generally known that the province offers exceptional facilities for the profitable pursuit of this branch of the chemical industry, because of its abundant water-power still unharnessed and its vast stores of the necessary materials.

Little is at present being made public as to the intended scope of the company's activities. However, they will, during the balance of the war, engage in the production of nitric acid for use in the manufacture of munitions, and when peace comes, in the production of fertilizer. The company is an American concern, with a capital of $2,000,000. The head office is in Seattle. An experimental plant was established some time ago in the State of Washington, and the success of that undertaking led to the expansion to British Columbia.

In the electro-chemical industry an abundant supply of pure limestone and coke in the vicinity of operation, and cheap electricity, are essential. The process is a simple one. Calcium carbide is first produced in an electric furnace from the limestone and coke. The calcium carbide is then raised to a red heat and nitrogen from the air passed over it. The nitrogen and carbide combine in the compound cyanamid. In its turn, this compound can be readily transformed into ammonia.

There are, of course, a number of slightly differing methods of electro chemical manufacture. The Badische Chemical Company of Germany use what is known as the Haber process in their plant, producing something like 500,000 tons of nitrogen products annually for the military uses of the enemy. Norwegian concerns favor the Arc process, by which a direct combination of the oxygen and nitrogen of the air is effected through the employment of the great heat of an electric arc. This process, to be economically feasible, calls for abundant and cheap electric power. At Niagara Falls, Ont., what is called the cyanamid process is employed, in which cheap power is also essential.

The American Nitrogen Products Company have adopted the Arc process. Their plant is being constructed close to the Lake Buntzen power plant of the British Columbia Electric Railway Company, with whom it is understood they have arranged for 3,500 kilowatts at a low rate, made possible by the delivery of the power at times when the British Columbia Electric Railway Company do not require it for other purposes, and because of the proximity which obviates the installation of extensive transmission lines and their subsequent upkeep.

New Power Scheme for Montreal Island

A second scheme for developing power on the Rivere des Praries, Island of Montreal, is projected, Messrs. J. R. Walker & Co., makers of sheathing felt, leather board, and friction board, having applied to the Quebec Government to construct a dam from the shore to Visitation Island, and a second dam from Visitation Island to Cedar Island. The power house is to be located on the Vincent de Paul side of the river. The company have a mill known as the Sault au Recollect Paper Mill. The scheme is understood to be in opposition to that of the Sault au Recollect Land & Power Company, referred to in our last issue, and which is backed by Senator M. J. O'Brien. The dam of the last named company would be higher up the river, but would skirt Visitation Island.

The Application of Synchronous Converters

By Mr. H. B. Dwight

When direct current is required in moderately large quantities, it may be obtained from the usual alternating-current power systems either by means of synchronous converters or by means of motor-generator sets. Of recent years, synchronous converters have been much improved, and have been gaining rapidly on the alternative apparatus, the motor-generator sets. Very large installations of converters have been made. For instance, the aluminum industry and the zinc industry have many thousands of kilowatts of converters in single installations. Many companies, including several very large steel mills, have recently adopted converters as their standard for the supply of direct current, instead of motor-generator sets, their previous standard. In railway work, converters are used in large numbers. In view of these facts, it is of interest to review the economies and advantages offered by synchronous converters.

The most outstanding economy effected by synchronous converters is the large reduction in first cost. It may be stated that, except for the smallest sizes, a motor-generator set will cost from 25 to 50 per cent. more than a converter of the same rating. This statement will apply even when the motor-generator can be installed without providing additional transformers. Transformers are always required with a converter.

An economy as important as the preceding is the higher efficiency of a converter and its transformers compared with the efficiency of a motor-generator set, even without transformers. For instance, the efficiency of a 500 kw. converter and transformers of usual characteristics is about 93 per cent. at full load, while that of a motor-generator set of the same rating is about 87 per cent. The difference is expressed more clearly by stating that the losses of the converter are 7 per cent., while those of the set are 13 per cent., or almost double. The cost of the extra power losses amounts to a large sum in a year, and may amount to 5 per cent. each year on the first cost of the converter.

One advantage of converters is that they are inherently able to commutate successfully very large overloads. This is especially useful in railway work, and some railway converters are guaranteed to carry momentary overloads of 200 per cent., that is, they can carry peaks of load amounting to three times their full load rating.

Synchronous converters can supply three-wire d.c. circuits at practically no extra expense, since the neutral can be brought out from the transformers, without the expense of collector rings and balance coils which are required with three-wire d.c. generators. Similarly, the neutral of a two-wire d.c. circuit can be easily grounded when a converter is used, and this will protect the d.c. circuit from abnormally high voltages.

The operating troubles encountered in the early years of the development of the synchronous converter, which created a feeling that motor-generators were more reliable, have now been substantially overcome, and it can be stated that synchronous converters are thoroughly reliable machines. It can also be stated that 60-cycle converters are practically as reliable as 25-cycle converters. Any commutating machine, whether converter or generator, will flash over when subjected to a heavy short circuit. The flashing of converters has been reduced so much in recent years that they are not at any disadvantage with respect to generators in this matter.

Synchronous converters cannot give the same easy adjustment of the d.c. voltages as can be obtained with genera-

ors. However, if the variation required is small, an induction regulator may be installed on the a.c. side. For somewhat larger voltage variation, up to 10 or 12½ per cent. from normal, booster converters have been used extensively. These have a small a.c. generator connected in series with the line, for changing the voltage. In certain cases low voltages may be obtained by providing taps on the transformers, and converters are now in successful operation in Canada which operate at approximately half voltage as well as full voltage by this means. Where the a.c. supply is subject to violent fluctuations in voltage or frequency, motor-generator sets may be preferable to converters.

The cost of development where special characteristics are required is heavier in the case of converters than in the case of motor-generator sets. Consequently, a standard converter should be specified instead of an odd rating. Where a standard converter cannot be used, as in the case of small sizes, or for the supply of current at 125 volts, a motor-generator set should be specified.

Converters can usually give flat compounding, that is, the same voltage at no load and full load. Higher compounding than this, while it may be desirable, is not absolutely necessary for most applications. In general, converters can operate in parallel with generators if the generators are changed so as to have the same compounding as the converters.

Synchronous converters must be operated at nearly 100 per cent. power-factor, especially for long-continued heavy loads, since low power-factor operation produces extra heating of the armature coils close to the collector ring taps. A synchronous motor of generous size and whose field current is frequently adjusted, can give much more power-factor correction or much more control of the voltage than a converter. It is a point worth remembering, however, that the most leading current is required at the time of heaviest load, and a converter, by means of its series winding, automatically provides this. On the other hand, a synchronous motor generator set may quite possibly have a lagging power-factor at times of overload, if the field rheostat is left at a fixed setting, as is often done, especially with the smaller units. Therefore, taking into account overload conditions, a converter may have almost as good effect on the power-factor and the voltage as a synchronous motor-generator set which is not carefully controlled. If the synchronous motor is large enough to be provided with an automatic voltage regulator, it will give the most leading current when it is most needed, and will hold the voltage constant by power-factor control, within the limits of its kv.a. rating.

In many countries, synchronous converters are used to an increasing extent for the supply of direct current in large quantities for railway work, electrolytic work and for d.c. motor loads. Converters are not yet used to an equal extent in Canada, and good results would be obtained if more attention were paid to the possibilities of this useful type of apparatus.

It is stated that the British Columbia Government may shortly undertake the electrification of the North Vancouver section of the Pacific Great Eastern Railway. There is said to be sufficient water power obtainable at three points to electrify the entire road to Prince George, although such an expenditure is not warranted at the present time.

The Toronto city council, it is stated, will take immediate steps to have the ban removed on store lighting, and also to have full street lighting restored. It is felt by many merchants that this would be a very considerable stimulant to Christmas trade.

Water Powers in the Maritime Provinces

By Mr. K. H. Smith*

Since 1915, active water power investigations have been carried on in Nova Scotia by the Nova Scotia Water Power Commission in co-operation with the Dominion Water Power Branch.

It has been necessary of course to give primary consideration to hydrometric work, that is the securing of adequate run-off data, of which none whatever were available in Nova Scotia prior to the inauguration of the work herein mentioned. During the past year, too, the necessity of making every possible man available for immediate military duty has further curtailed detailed power and storage surveys.

However, power investigations to date in Nova Scotia have revealed power sites with a total 24-hour capacity at all seasons of the year of about 100,000 horse-power. Maximum advantage of all these sites may be secured due to the large storage reservoirs at each site. Under such conditions, the installation warranted for the sites in question for ordinary commercial purposes would be from two to three times the 24-hour capacity given.

It is to be understood that the estimate given above is only for such power sites as have been investigated to date, and that a number of rivers on which power sites of considerable magnitude are known to exist have not yet been investigated. It should be noted, too, that a water power site located at any place within the province of Nova Scotia is within easy transmission distance of some industrial centre or shipping point.

At its last session the Government of Nova Scotia passed a Water Power Act designed to place the local government in control of all water powers with a view to removing as far as possible, legal obstacles, and facilitating in every way legitimate water-power development. The effective carrying out of this Act depends upon regulations which have not yet been put into force, but it is expected that such regulations, worked out in co-operation with other parts of Canada will be made operative at an early date.

During the past summer, a water power commission, consisting of C. O. Foss, Chairman, B. M. Hill, and W. E McMullen, Secretary, was organized in New Brunswick. The members of the Commission are all employed by the New Brunswick government in other capacities, and it is especially noteworthy that they are all engineers.

This Commission entered into a co-operative arrangement with the Dominion Water Power Branch, Interior Department, Ottawa, similar to that in operation in Nova Scotia. Water power investigations in the provinces of Nova Scotia and New Brunswick, including hydrometric surveys may therefore be carried on by a single engineering organiation which results in maximum economy and efficiency.

As was the case at the beginning of investigations in Nova Scotia, attention is being concentrated in New Brunswick on hydro-metric work. While New Brunswick was in a somewhat better position in this regard than Nova Scotia due to the activities of the bordering state of Maine and of the former International Commission, pertaining to the St. John river, still there were run-off data for the greater part of the province. Although active work was not begun until August, 10 gauging stations had been established up to the end of September, and about 20 current meter measurements made. It is considered that these stations with one or two

*District Engineer, for the Maritime Provinces, of the Dominion Water Power Branch, Department of the Interior.

...gauges to be established and those now or formerly maintained by the United States Geological Survey will give fairly satisfactory run-off data for all parts of the province.

It may be interesting to note that results from one of the new gauging stations, that on the Madawaska river, are of value to the province of Quebec, as well, and as the station is actually located in that province, the Quebec officials are assisting in its maintenance. In this particular instance, therefore, there is co-operative action between the Federal government and the two provinces of New Brunswick and Quebec with one other province, Nova Scotia, indirectly interested.

Possibly some delay in undertaking water power investigations in New Brunswick may be attributed to the fact that in the past, there has been a general impression that the province of New Brunswick was deficient in water-power. Exception was made in the case of one or two outstanding powers which were too large or too far removed from industrial centres to warrant immediate development and certain international powers on the St. Croix river.

In the course of a reconnaisance of the province primarily for the location of steam-gauging stations, a number of small moderate sized sites have become apparent, some of which offer promise of economic development at an early date, either individually or in conjuiction with others. At the same time, it is quite possible that some sites which have not been considered favorably hitherto, due to a lack of storage reservoirs and a consequent great diminution of power at certain seasons of the year, may be developed in connection with steam generating stations located at some of the New Brunswick mines to great advantage from the standpoint of cheaper power and conservation of coal resources.

For obvious reasons there has been very little actual water power development in the Maritime provinces recently.

In Nova Scotia a water power plant supplying the town of Oxford, has been improved and enlarged, including the construction of a steam reserve to utilize mill waste near at hand. The village of Lawrencetown, Annapolis County, is now installing a water power plant on the Annapolis River immediately in the village to replace a steam generating plant, the cost of operating which was found prohibitive. The town of Annapolis Royal has also made a start towards increasing the storage capacity of their municipal water-power plant.

Middleton recently bought a water-power plant about three miles from the town, which had been inoperative for some town. With a few minor repairs and the building of about 3 miles of transmission line, this development was put into service at once, replacing a gas-producer generating station. In addition to its former lighting load, the town is now supplying industrial power, and recently connected up the largest individual power user in the community who formerly had steam equipment.

In New Brunswick, a small water power development was completed some months ago to supply lighting, and industrial power in small amounts for the towns of Rexton and Richibucto. At the present time, a 2000-kw. hydro-electric station of excellent design and construction is being built on the Madawaska river at Edmundston. This development is intended to supply power for a large sulphite mill also under construction at the same place for Fraser Companies, Ltd.

In general, it may be said, that never before in the Maritime provinces were so many major power projects under serious consideration, and it seems quite probable that considerable development will take place at the first favorable opportunity. In a few cases, responsible parties are pressing to have the legislation recently enacted in Nova Scotia as outlined above made operative.

Official Meeting of American Institute of Electrical Engineers to be Held in Toronto, November 22 and 23

It is just fifteen years since a number of prominent electrical men of the city of Toronto formed the Toronto Section of the American Institute of Electrical Engineers. During these years the section has reflected the increasing electrical importance of the city and province. During the present year they captured the pennant for the greatest percentage increase in membership during a campaign which was conducted by Mr. A. B. Cooper and his committee.

In recognition of the position the Toronto Section has attained the directors of the Institute have decided to hold an official Institute meeting in Toronto on Friday and Saturday, November 22 and 23, 1918. Full particulars of this meeting are appended and every member is urged to contribute to its success by attending the technical sessions, joining in the discussions, being present at the dinner at the Engineers' Club on Friday evening, and by bringing his friends along. We are confident this meeting will prove one of the best electrical functions ever held in this city; it should demonstrate not only the activity but also the sociability of the electrical engineering fraternity.

On account of the influenza epidemic two very interesting papers have been cancelled; this ought to make every member enthusiastic about the big November meeting. A most cordial invitation is extended to members and friends to come along and renew acquaintance with old friends and take an active part in the proceedings.

PROGRAMME

Friday, November 22

1.30 p.m. Paper by Mr. Arthur H. Hull, Chairman, Toronto Section, "Electric Power Development in Ontario."

3.30 p.m. Paper by Mr. W. G. Gordon, Transportation Engineer, Canadian General Electric Company, "The Electrical Equipment of the Canadian Northern Tunnel in Montreal."

5.30 p.m. Adjournment.

6.30 p.m. Dinner at the Engineers' Club for Members, Delegates and Friends, price $1.75 per cover.

7.15 p.m. Address by Sir Robert A. Falconer, C.M.G.

8.00 p.m. Paper by Mr. S. Svenningson, Designing Engineer, Shawinigan Water & Power Company. Montreal.
"A Long 110,000 Volt River Crossing."

10.30 p.m. Adjournment.

Saturday, November 23

9.30 a.m. Assemble at the Engineers' Club for one of the following visiting trips:
(a) Leaside Munition Plant, Leaside, Ont.
(b) British Forgings Company, Electric Steel Plant, Ashbridges' Bay, Toronto.
(c) Hydro-electric Substation and Laboratories, Strachan Avenue, Toronto.

(Members should register on Friday for which ever trip they desire to make; automobiles will be provided by the accommodation is limited).

Executive, Toronto Section, 1918-1919

Arthur H. Hull, Chairman, Ashton B. Cooper, W. Percy Dobson, Herbert B. Dwight, Frank R. Ewart, William G. Gordon, Gordon R. Langley, William Volkmann, Ernest V. Pannell, Secretary.

Reception Committee

E. M. Ashworth, W. M. Andrew, E. T. J. Brandon, R. G. Black, W. A. Bucke, F. G. Clark, H. C. Don Carlos, F. A. Gaby, W. G. Gordon, H. U. Hart, Jas. Kynoch, G. D. Leacock, Wills Maclachlan, W. R. McRae, D. H. McDougall, A. L. Mudge, T. R. Rosebrugh.

Electric Welding—A New Industry

By Mr. H. A. Hornor*

About a year ago the Chairman of the Standards Committee of the Institute was requested to investigate and standardize spot welders and the apparatus connected with them. It occurred to the members of this committee that electric welding could perform an important function in increasing the progress of steel ship construction. The work which was started by the Standards Committee was then transferred to the General Engineering Committee of the Council of National Defence. Last winter the Council of National Defence abolished all advisory committees but at this time the Emergency Fleet Corporation of the U. S. Shipping Board had become so much interested in the subject that they decided to adopt the committee. The committee is composed of representatives covering broadly the whole field of welding activities in this country and, although electric welding has been the subject of all the investigations up to the present time, it is now proposed to include gas welding with representatives from all the gas welding associations and companies connected with the industry.

The two main processes of electric welding, namely, arc welding and spot welding, were found by this committee applied in the first case to repairs and in the second case to certain factory quantity production jobs. The work done was in the case of spot welding only on light material, and in neither case very extensive. The processes to be successful in their application to the construction of merchant vessels would have to show reliability in the joining of steel plates from a half-inch to one inch in thickness. To this and kindred problems the committee immediately turned its attention.

The work had all been done in the field where it had been applied by practical men. It was first necessary to formulate the proper nomenclature and symbols. This was thoroughly investigated and a very comprehensive set of symbols has been approved by the committee and is in daily use by those now actively engaged in this new application. The approved nomenclature introduces the subject to the designing and calculating engineer and gives him the instrument by means of which he is able to place his thoughts rapidly and conveniently on drawings.

The manufacturers of apparatus joined the practical man in the study of the problems of electric welding. Apparatus and so-called processes introduced various types of machines suitable for the conversion of electrical supply to the proper values of current and voltage needed at the arc or at the spot. The manufacturer in his eagerness to meet the problem naturally encountered many difficulties. These difficulties increased until a point was reached as referred to above where he demanded some standards upon which his apparatus could clearly be rated. Therefore, the manufacturer was only too pleased to co-operate with the Welding Committee and is to-day conscientiously aiding in straightening out the difficulties in which he was involved prior to last year.

Arc welding in this country has largely been done in the railroad repair shops. It was discovered that the process was much cheaper and could be performed more rapidly than by any of the gas welding methods. It also could be applied without preheating and in many cases without the expense of disassembling complicated pieces of machinery. Spot welding besides being used in many different industries was sought for by the railroad man and there has been built a gondola car which has seen some seven or eight years of service. It is interesting to note here the difference in practice between Great Britain and the United States. The former knowing little or nothing about spot welding had the practice and application of arc welding very well under way; the latter exactly the reverse.

Apparently the attempts to train operators were rather crude and it was early observed that the reliability of the electric weld depended substantially upon the skill of the welder. The manufacturers of apparatus and the superintendents in railways shops had struggled with the problem of training operators but intensive study had not been given the subject so that there existed in this respect a great deal of groping in the dark.

Present Status of Electric Welding.

Investigations were immediately undertaken to answer the question whether spot welding could be successfully accomplished using one-inch thick steel plates. An experimental apparatus of large size was erected and put into operation, the results showing that no difficulty was encountered with half-inch and three-quarter inch plates. The same remark applies to one-inch steel plates. In fact, this experimental machine was successful in welding three thicknesses of one-inch plate a condition which far exceeds the requirements of merchant ship construction. This operation has its historical significance in that this was the first time that any spot welding of this magnitude had been performed. The successful outcome of these experiments has led to the design and construction of large spot welders to be used in the fabrication of ship sections. The practical application of a large five-foot spot welder will be made at a demonstration of a forty-foot section of a standard 9600-ton ship to be built at the plant of the Federal Shipbuilding Company, Kearney, New Jersey. This is the largest portable spot welder ever built. It will prove two points in ship construction by the electric method, namely, the clamping of the ship's structural parts for assembly thereby reducing the time in working the material as well as for the erection of the ship material; and secondly, by the speed of spot welding it will prove the decrease in time for joining the material together. The consensus of opinion is that the large stationary spot welder of five or six-foot gap will undoubtedly play an important part in increasing the speed of fabricating sections of standard steel vessels. Further investigations are being made and designs are being worked out for special spot welders for use in the construction of bulkheads. The designs proposed are chiefly for shop processes, but it can be asserted that such apparatus will be of undoubted value in the saving of time and man power.

Arc welding had been tried in a great variety of work but there was no conclusive evidence that it could be developed to the stage of joining ship plates with the certainty of full strength. The first stage of this investigational work is now almost completed. Sample welds of half inch ship structural steel were taken by a special sub-committee to fourteen or fifteen different places where electric welding was done, noted the conditions of current, voltage, electrode, operator, etc., and then prepared the welded samples for tests. The samples were forwarded to the Bureau of Standards in Washington so that the tests should be conducted by parties absolutely disinterested and without knowledge of how the samples were obtained. The results of these tests showed a remarkable similarity especially when it is realized that they were made by several firms with different electrode materials and under varying conditions of the electrical cur-

*Read before the A. I. E. E.

cent. Practically all of the welds pulled at over 50,000 pounds per square inch and several over 60,000 pounds the average being about 58,000. On the bending test one of the samples was bent to an angle of 78 degrees before a crack started and final failure reached 80 degrees. In another case the sample was bent to 65 degrees before the crack started and final failure did not occur until 86 degrees. The point of importance here is that all the welds showed a reliability and satisfactoriness which makes conclusive the opinion that electric arc welding is applicable for the joining of steel where the structure is submitted to live loads, bending strains, static pressure, or the like. The Sub-committee on Research is pursuing this subject and practical samples are being prepared for similar tests using three-quarter and one-inch stock material. The results of these tests will be available as soon as the reports are presented and approved by the Welding Committee. The Research Committeee is also preparing various types of joints in heavy plating. These will be submitted to all the regulation tests and in addition to shock and fatigue tests and tests to destruction.

To give a further indication of the large size practical tests which are being carried on at the present time it may be stated that three 12-foot cube electrically welded tanks are now being constructed. These tanks are built in such a way that from twelve to fifteen different designs of joints are used in their construction. After these tanks are built they will be subjected to a static strain and the deflection of the seams will be directly measured. Afterwards they will be tested by external shock and crushed to destruction. Portions of the joints will be cut, sent to the Bureau of Standards, and again tested for the sake of accumulating precise data. In this connection there is being built at the Norfolk Navy Yard a battle-towing target. The keel of the target 110 feet long will be entirely electrically welded and the results of this practical demonstration will be carefully recorded after it has been put in regular service.

Alternating Current Found Advantageous.

It is to be expected that the manufacturers of apparatus being keenly observant of the increased interest in electric welding as well as in the future, which is probably now unquestioned, would be active in their desire not only to improve their present facilities and their design of apparatus, but also to proceed themselves to follow the trend of the investigations made by the Welding Committee. The consequence of this has been a large increase in output of apparatus that is needed. One interesting point is that certain manufacturers who were decidedly of the opinion that direct current was the only proper current to use for arc welding have within a very recent period changed their point of view and are willing to admit that alternating current may have certain advantages in the development of this art.

The electric arc requires a reduced voltage and this is difficult to attain with direct current without relatively expensive machines or a useless expenditure of energy. The practice in this country in manufacturing establishments of any size has been toward an increase in the supply voltage so that very few large manufacturing plants use less than 220 volts direct current. With this voltage the only economical method of transformation is in the use of a motor-generator set. The efficiency in this case is in the neighborhood of 50 to 60 per cent. It is possible to use a supply voltage of 110 volts with a variable resistance which cuts down the voltage to the arc volts. This gives a very poor efficiency. In the case of alternating current the supply voltage can be reduced by a transformer which will supply as in the case of direct current a sufficient voltage for striking the arc and a satisfactory reduction when the arc has been struck. On the other hand, if a low voltage alternating current is provided a simple reactance may be introduced which has some of the same wasteful characteristics of the resistance used with the direct current. The average apparatus will permit of electric arc welding consuming about six to eight kilowatts per welder, but if low voltage is provided there are certain outfits which will reduce the consumption as low as three and one-half kilowatts per welder, or even less.

Without entering into an elaborate analysis of the relative costs of electric welding, it may be broadly stated that there is hardly any question that the electric process is cheaper than any other. The same may be said as regards speed and also reduction of man power. In a recent discussion of this subject President Adams stated that at one of the Eastern shipyards the total number of parts on the welding program of the standard riveted ships now building at that yard amounted to 225,000. The labor cost for riveting these pieces is about 245,000 dollars and for welding about 99,000 dollars making a saving of 146,000 dollars. But this is only a drop in the bucket when compared to what might be profitably done in this line. He stated further that in certain particular instances the saving is as great as 90 per cent.

One of the interesting questions discussed with some fervor by the members of the Welding Committeee is the advantages of the bare and covered electrode. Regarding this discussion no definite facts can be stated. In England the practice has been to use the covered electrode which protects the welding arc from contact with the air thus guarding against too great a formation of oxide. The practice in the United States up to the present time has been largely bare wire. Recently, American investigators have discovered the important fact that there are advantages in the covered electrode and many experiments are now being made, some with results. It is important to observe that in the above mentioned tests of welds, the best one of these samples was made with a coated (not an asbestos covered) electrode using alternating current. The point in this case seems to rest upon the question of the ducility of the weld and it would seem that the bare electrode does not make as ductile a weld or at least one as easily bent as the coated or covered electrode. The question of the ductility of the weld is one of much importance in the application to ship construction and will doubtless be of importance to other allied industries. It is, therefore, a question of serious importance and constitutes an important part of the work of the Sub-committee on Research.

No matter what the type of electrode is nor its composition, no matter what kind of shank material is to be welded, no matter what kind of apparatus is employed, the reliability of the weld rests mainly upon the man who welds it. This man if he has been properly trained and is skilled in the art knows instantly whether he is making a weld or not. He becomes after much practice able to judge fairly well upon looking on a finished weld whether it is a good weld or not. The work of training electric welding operators early became a part of the functions of the Education and Training Section of the Emergency Fleet Corporation. The men connected with this work are members of the Welding Committee. Schools for the training of operators as well as for the conversion of operators into instructors, are established in many parts of the country. The objects held in view by the training department are first to give the man intensive practice work so that he becomes a good craftsman. The methods are simple to start with, as the exercise of the right arm muscles must become flexible enough to permit the operator to give the required movement to the electrode. By a graduated series of exercises this is accomplished in about eight weeks. The man is allowed to do production jobs in the shop which gives him confidence through responsibility. It becomes desirable at this time to give the man some outside work on ships and where this is practicable it is done. The man is then turned over to an instructor who gives him an intensive

course in pedagogics lasting from five to six weeks. At first sight it would not seem necessary to so instruct a man but it is not generally understood that teaching after all is itself a trade. The experience with the men in this respect is most interesting. In nearly every case the man has resented this course at the start but at the end has turned completely around and in many cases has desired an even more extensive training. What is really accomplished is to give the man the necessary confidence to impart the knowledge that he has gained to another green man. The men under training are taken from the various industries especially the shipbuilding industry and after they have finished their instructor course are returned to their employer to carry on the instruction, in their own plant. The men who go through this training as provided by the Emergency Fleet Corporation are certificated when they have shown themselves to be entirely proficient. It is not possible nor expedient for the Emergency Fleet Corporation to require the certification of all electric welders. It is the consensus of opinion that all industries doing serious work with the electric arc should use men who are certified as to their ability in the art of electric welding. The main reason for this opinion is that the operator must be a conscientious workman or the weld will not be of perfect quality.

This brings forward another problem upon which a great deal of experimental work has been and probably will continue to be done, namely, a practical and scientific method of testing a welded joint it has been made. There have been a number of suggestions made for the solution of this problem. They are briefly, as follows:

(a) Mechanical. By hammering the weld or by chipping at frequent intervals.

(b) Electric. By means of resistance or voltage drop.

(c) Magnetic. By means of the permeometer or the change of conditions of the magnetic circuit.

(d) X-ray. By means of an exposure on an X-ray plate.

At the present time none of these suggested methods have been productive of conclusive results and recourse must be had to the purely mechanical methods of striking heavy blows on, or adacent to, the weld or by using a chipping hammer and making intermittent examinations. It would seem by far the best procedure to make the inspector proficent in the art so that he may closely observe the welders while at work. This may be accomplished by a two or three weeks attendance of inspectors at any one of the electric welding training centers.

Methods of Electrice Welding.

There are many methods and processes of electric welding but the two main ones that interest the committee at the present time and alone have been mentioned so far are the spot welding and arc welding. It may be a surprise to some of the old time welders to consider electric welding as a new industry. In substantiation of this statement it may be well to describe briefly what is meant by electric welding as it is practiced to-day.

Spot welding is not much different in the methods of procedure or in design of apparatus than when it was first introduced. Copper electrodes, water-cooled in the heaviest machines, are placed on opposite sides of the material to be welded together. The joint is a lap joint. Machines are now so designed that two spot welds may be made at one time. The routine of the operation is as follows:

The electrodes are brought into contact with the materials to be joined, current is supplied sufficient to give the required heat, pressure is then applied, the current is removed, and the pressure is removed, the weld is then complete.

The operator has a perfect indication of making a good spot weld by the use of a button placed under the electrode observing which he knows exactly the proper timing of the operation. There is therefore no question as to a good, bad, or indifferent, spot weld. Automautic spot welders have been designed and built, but it is the general opinion that they add complication to a process which in itself is very simple.

The process of arc welding is as follows:

One side of the electric circuit is connected to the material to be welded, the shank material is usually prepared by bevelling the edge of the pieces to be welded together. The other side of the electric circuit is connected to the electrode. By touching the electrode to the shank material the arc is drawn. The skilled operator now moves the electrode from side to side of the groove giving a semi-circular motion while at the same time moving the electrode along the groove.

It is important that the arc "bite" into the shank metal creating a perfect fusion along the edges and the movement of the electrode is necessary for the removal of any mechanical impurities that may be deposited. In the coated electrode it is further necessary that the slag which forms for the protection of the pure metal be worked up to the surface and it is extremely important in the event of a second or third layer that the slag or impurities be carefully scraped away before the virgin metal is again laid on.

The operator in arc welding is protected with either a hand screen covering his face with special glass through which to observe his work. The electric arc emits dangerous invisible rays in both the upper and lower spectrum scale and it is quite evident that both the infrared and ultraviolet are dangerous in their effect, the former is pathological the latter actinic. The operator further uses gloves for his hands and for the very difficult work of overhead welding it is necessary for him to use a helmet which partly covers his breast.

Developments.

The tendency of developments in spot welding has already been slightly touched upon. In their nature as applicable to shipbuilding the advancement will naturally have to proceed toward means for accomplishing spot welding in very cramped locations. This makes an exceedingly difficult problem as the power requirements are such as to preclude any very small device. In riveting one-half of the apparatus is on one side of the work and the other half on the opposite side and it is difficult to conceive of any method of spot welding that will admit of such an arrangement. In shipbuilding it is quite probable that designs may be made that will permit of a large or at least increased amount of spot welding in the actual construction of the vessel. Certainly, present designs of riveted ships will not allow of this to any great extent. As already stated, spot welding can now take its place in the fabricating shops and it is to be expected that within a few months spot welding will begin to supplant riveting in this field. The only drawback to this will be the sufficient production of spot welding apparatus.

The tendency of development in arc welding is toward the automatic machine to obviate the responsibility that has to be placed upon the skilled operator. Intensive work has been done within the last few months in the line of automatic arc welding machines and at the present time sample tests of welds made by such apparatus have been sent to the Bureau of Standards. These machines will occupy a very important position in repetition work. They will not immediately supersede the skilled operator in repair work, or in special jobs but it may be expected that the development of such machines will bring apparatus which can be man-handled and will eventually take the place of most of the hand work as it is now known.

Of the scientific advancement in the art of electric welding there is so much to be treated that only a general outline can be considered at this time. The research work has only just begun. Practice has preceded the scientific investigation.

The field, therefore, is full of most interesting problems. Those who have been following the development of the past six months are deeply interested to know the fundamental reasons. The investigational questions may be grouped into three main divisions:

1. Metallurgical; 2. Physical; 3. Electrical.

The metallurgist has yet to tell us what the conditions of the metals are after the electrode material has fused with the parent metal, and to determine what the proper conditions must be to produce a good weld. This problem has in it a great many variables. The physicist must explain the atomic or electronic conditions which permit of the combinations at the high temperatures involved and must explain the phenomenon of overhead welding. The electrical investigator must determine all the various phenomena connected with the preferences between and the advantages of the use of different forms of electrical energy and the varying characteristics of the electric circuit in producing different type of welds.

Conclusion.

From the preceding remarks it must be conceded that the Welding Committee of the Emergency Fleet Corporation has already crystalized the problems connected with this art. The working functions of this committee have been laid down upon the broadest possible lines. Liberal opportunity has been given every one to state in detail his opinion and to express the reasons for his preference on every point connected with this subject. The committee goes even further than this. It furnishes those interested with every new idea that is brought to bear upon the subject after sifting from the suggestions any question of doubt or misstatement of fact. All suggestions of improvement or problems of special application are gladly taken in hand, thoroughly investigated and reports made. It will welcome any comments that those connected with the industries may desire to lay before it. The personnel is at the present time such that it can devote not one but many minds to the solution of any specific problem that is laid before it.

The committee early discovered that the literature of electric welding was very much clouded by misstatement of fact or half-baked theory and much of the time of the committee has been taken up in disproving such statements. In order to spread the results of this work to all quarters a handbook is now being prepared which will contain only definite facts and results of investigations as are approved by the whole committee. This handbook will be made available to all those who desire to acquaint themselves with the proper means of accomplishing good and reliable electric welding.

Why Single Out Electric Railway Companies for Condemnation

The opposition to increased fares on the Winnipeg Electric Railway System has advanced the argument that the company ought to have built up a sufficient reserve to carry them over this period of high prices. So, perhaps, they should. So, also, should every other of the thousand and one business concerns operating in Canada. Unfortunately, however, they didn't know what was coming and the un-understandable feature of the whole situation is that street railways should be singled out for unjust treatment. Where is there in Canada a single commodity that has not gone up in price, except street railway fares. General Manager McLimont, of the Winnipeg System, is quoted in reply to this criticism as follows:

"How much money did you save during the boom days—the days of prosperity before the war?

"Did you lay aside a reserve during those prosperous, piping times of peace, in anticipation of these stressful seasons of war?

"The argument has been advanced, in connection with the Street Railway situation, that the Winnipeg Electric Railway Company should have laid aside, during the days of financial plentitude, a reserve which, in the eyes of the critics, should have been sufficient to enable the company to continue selling its product—transportation—during war-time, at pre-war prices.

"It is a great idea—on the surface. In a nut-shell, the Winnipeg Electric should have done what no other corporation, firm, merchant or individual citizen did, and should thereby have demonstrated a vision unparalleled on the North American Continent and a foresight outrivalling that of any human being outside of Berlin.

"The only thing that prevented the company from doing differently from anybody else, was the fact that the authorities at Potsdam failed to 'tip off' the Winnipeg Electric Railway Company to what was impending. The Kaiser and his confederates hatched up the plot when the detectaphone was out of order.

"If one started in to condemn everybody whom the war has placed in a position of temporary financial embarrassment in this Western country, the Kaiser's projected war of 1940 would be started before the work of condemnation could be satisfactorily concluded.

"The Winnipeg Electric Railway Company now has to meet an uncontrollable difference of more than $600,000 between the money it earns and the money it has to pay. The largest proportion of that sum is represented in wages, which will be circulated by more than a thousand families in and around this city.

"It would be futile to turn to those families and tell them that they should not ask employers for increased revenue to meet the increased cost of living, and that they should have saved up during pre-war times, enough money to carry them over until the end of the war without any increase in wages.

"Is it not equally inconsistent to tell the company what you would think it folly to tell its employees?

"The $600,000 has to be found in order to keep the service running. The company is not asking for money to pay dividends. Dividends? Why they are now merely a distant recollection—just like the savings accounts the workingmen had before the war.

"After most careful computation it is found that a six-cent fare will yield this company only just revenue sufficient to meet its outlay under these new war burdens. This company was prosperous once—at a time when everybody else was prosperous, during the boom years, when everybody, including the Winnipeg Electric, was spending money as freely as everybody else, with abundance of faith in the future.

"The C. P. R. paid dividends before the war; it has paid dividends ever since the war began. It has no deficit. But when the Railway War Board increased railroad workers' wages and the C. P. R., with other roads, asked an increase in freight and passenger rates, did the Dominion Government or the Railway Commissioner say: 'No, you should have set aside a big reserve in the palmy days before the war?' The increases in freight and passenger rates were granted.

"Why single out the Winnipeg Electric Railway Company and condemn it for being temporarily embarrassed by war-enhanced expenses? The company is confident that thoughtful citizens will co-operate in order that its public service may continue and that employees dependent on it may receive a living wage."

The Montreal Tramways Company have let contracts for repairs and extensions to their car barns at Vitre, de Fleurimont, and St. Antoine Streets.

Photometry and its Application to Commercial Needs

By Mr. Geo. G. Cousins*

Photometry is to the illuminating engineer what the rule is to the carpenter, the scales to the grocer, or the thermometer to the chemist. It has made possible the vast accummulation of data on which the science of illuminating is built and furnishes a means whereby the accuracy of the theory is checked. Photometry and illuminating engineering have advanced hand in hand. The advances made in illuminating engineering have been made possible chiefly by the use of photometry and on the other hand photometry has been developed to meet the growing demands of the engineer.

The first literature on the subject was a book published by Lambert in 1770. Until recent years photometry was used only to measure the candle power of light sources, but its use is now very extensive and includes many uses not thought of until recently. The earliest experimenters in photometry realized that the strength of light could not be measured directly but that the intensity of one light could be expressed in terms of that of another which thus becomes an arbitrary standard with which the unknown light must be compared. This is the principle of all practical photometry at the present time.

Photometry is used at present mainly for the measurement of candle power, flux, illumination intensity and surface brightness. This classification does not include spectro-photometry and objective photometry, the one being a rather specialized branch and the other a method by which the human eye is eliminated as the measuring instrument. The eye simply reads the result of the measurement by observing the position of a pointer on a scale. Objective photometry is based on the principle that under certain conditions small currents will flow from certain metals when exposed to light. These currents are proportional to the intensity of the light causing them and are used to deflect a mirror of a galvonometer or electrometer, the magnitude of the deflection indicating the intensity of the light. This has not yet graduated from the experimental laboratory and it is necessary for us to fall back on the eye as the final referee; upon its ability to judge equality of brightness, or to detect small differences of brightness, depends the success of a determination. The eye is effective in making such a determination with any degree of accuracy only under precise conditions. The two lights being compared must be of the same color when presented to the eye. If a difference of color exists in the lights themselves some means must be used to change one or both. The most commonly used method is the use of colored glasses to absorb some of the excess color of one light. The transmission of these glasses must be known and compensated for in the interpretation of a result.

In a laboratory where conditions are under good control a flicker photometer may be used to measure lights of different color. This presents the two colors alternately at such a rate that the resulting sensation is that of a single color, which is a blending of the two. The speed of the alternations must be such that the flicker disappears when the photometer head is at a certain point between the two lights and reappears with a slight motion one way or the other. In other words, when both lights are of the same intensity at the photometer head the flicker disappears and the slowest speed that will accomplish this is the most sensitive for the instrument.

A discussion of photometry naturally leads to a discussion of light sources and each has its effect on the other. Some types of photometers are suitable for the measurement of some light sources and not for others. The advent of the gas-filled lamps caused more extensive changes in the practice of photometry than any other single event for a great many years and it might be well to consider the differences between the vacuum and gas-filled lamps that necessitated such changes.

Before gas-filled lamps appeared on the market the vacuum lamps were commonly rated according to their mean horizontal candle power and this rating gave a very fair means of comparing different lamps of the same type. However, for many years lamp and illuminating engineers, especially the latter, had realized that this rating was not altogether satisfactory. In order to use existing lamp data in illumination calculations it was necessary to convert the value of candle power, which is the intensity,, into one of total light flux, the unit of which is the lumen. This conversion is done by determining the ratio of mean spherical to mean horizontal candle power and then multiplying the mean spherical candle power by the factor 12.57 (4π) to obtain the lumens. This ratio of mean spherical to mean horizontal candle power is constant for vacuum lamps of each type, but its determination is a long tedious job. In spite of its short-comings, however, the candle power rating had become so deeply rooted that it was too big a task for any isolated body of engineers to make a change.

Now when gas-filled lamps were measured for mean horizontal candle power in the ordinary way some very peculiar results were noticed. With the lammp stationary, the candle power was lower and the current higher than with the lamp rotating at the ordinary speeds, at the same voltage. This higher efficiency while rotating is caused by the gas in the bulb being thrown outwards by centrifugal force to the walls of the bulb. This left the filament in a more rarified atmosphere and of course was not cooled to the same extent by the gas as when stationary. The temperature increased, which in turn increased the resistance and the current consequently decreased. At every change in speed there was a change in efficiency. A peculiar feature of this is that starting with the lamp stationary and slowly increasing the speed of rotation the efficiency at first decreases then increases and at one speed is the same as the stationary efficiency. This speed is usually about 20 to 40 r.p.m.—not enough to overcome flicker. This condition put a serious damper on lamp rotation. It was found that in some lamps there were fairly large differences in candle power in different horizontal directions and the candle power in one direction might not be anywhere near the m.h.c.p. Again it was discovered that for lamps of the same make and construction there were considerable differences in the spherical reduction factor, and that the spherical reduction factor varies during the life of a lamp. Here is another fundamental difference between vacuum and gas-filled lamps: in a vacuum lamp the filament material as it is evaporated travels in straight lines to the bulb the same as the light and the result is that at any stage of lamp life the blackening at any portion of the bulb is proportional to the amount of light passing through that portion. This results in the spherical reduction factor remaining constant throughout life. The gas in the gas-filled lamps rises as soon as it is heated by the filament and these currents of gas carry the evaporated filament material to the upper part of the bulb and the mean spherical c. p. decreases more rapidly than does the mean horizontal c. p.

In view of these difficulties it was quite evident that a new method of measuring was needed. Here was a condition that

*Before a meeting of Toronto members of the Illuminating Engineering Society.

made necessary the adoption of a rating based on the total flux of light from the lamp, the method that had been advocated for years but which lacked a condition of necesity to compel its adoption. At that time there were several different types of integrating photometers in use in various laboratories, but none gave such promise of adaptation to the peculiarities of the gas-filled lamp as the sphere and its use has become universal. The sphere can also be put to many different uses as will be described later.

Routine Photometry.

Now for routine photometry. The measurement of vacuum lamps should by precedence come first. This branch of photometry is about the simplest of any. A vacuum lamp does not mind what position it is burned in and has no definite peculiarities that demand extra precautions in its measurement. Vacuum lamps are the most suitable lamps to use as standards and this results in a good color match. In our own laboratory acceptance tests are made on vacuum lamps on the m. h. c. p. basis. The lamps are measured for c. p. and watts and target diagrams are made on which the

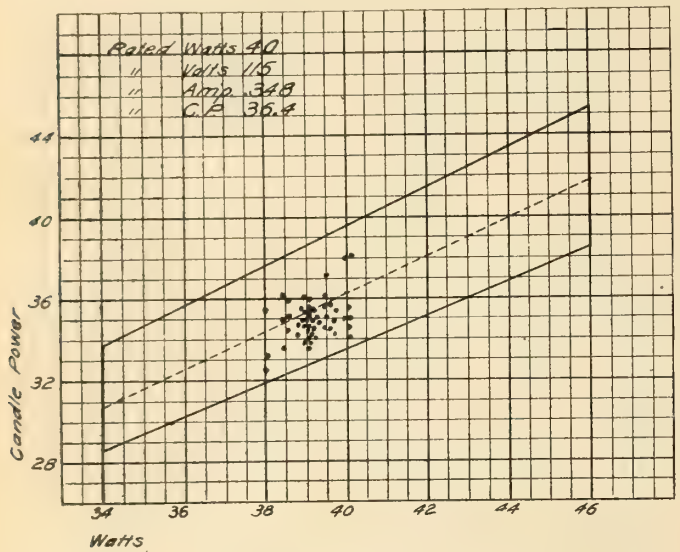

Fig. 1—Target diagram showing the measured efficiency of 40-watt tungsten lamps

rating of each lamp is shown by the position of a dot on the diagram, Fig. 1. The comparison device used for this work is the old familiar Bunsen screen. Speed is of more importance than a high degree of accuracy and the Bunsen screen permits speed of operation with a minimum of eye-fatigue. As lamps are being so measured one lamp out of each tray of 50 that is near the average watts and c. p. is selected to be further measured for life test, with more care as greater accuracy is required. For this purpose a Lumner-Brodhun photometric device is used and is capable of very high accuracy. Life testing of stock lamps is done at rated efficiency and the voltage is adjusted to produce the required efficiency.

The photometer on which this testing is done is not unlike others built for the same kind of testing but a brief description of it may be of interest. The comparison lamp is at the right end and the test lamp socket at the left; the distance between them is 100 inches. A batch of lamps being measured may include a range of from 10 to 100 watts and with such a wide range one candle power scale cannot include all and we have found it necessary to use three. These are calculated for 16, 32 and 48 c. p. comparison lamps respectively. If three comparison lamps of these c. p.'s were used it would necessitate that each be calibrated separately and this requires considerable time. In order to overcome this we use one lamp that normally burns at 48 c. p. and it is calibrated by using standards of 22, 36 and 100 c. p. These are placed in the test lamp socket one at a time, the photometer head is set at the rated c. p. of the standard and the voltage across the comparison lamp is adjusted until a balance is obtained. With the standards mentioned these balances occur at the ends and near the middle of the c. p. scale and the average voltage of the comparison lamp is taken as its working value. When it is desired to use the 32 c. p. scale with this lamp, a rotating sectored disk is placed between it and the photometer head. This particular disk cuts off 1/3 of the light and the effective c. p. then becomes 32. In a similar way the 16 c. p. scale is used with a sectored disk that cuts off 2/3 of the light. By this means we have a range of from 6 to 125 c. p. with one calibration of the comparison lamp. The change from one scale to another involves but a moment of time. This range includes all the vacuum lamps likely to be met with. In operation the photometric observer sets the voltage of both lamps and observes the c. p. The other operator reads the current or watts and does the recording. The test socket is made in 4 sections held in position by an endless spiral spring so that when the socket is rotating lamps can be placed in or taken out without stopping it.

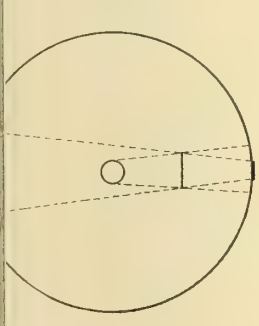
After all I have said about the lumen rating you may be wondering why our tests are made on the c. p. basis. This is because our specifications have not been changed since the lumen rating has come into general use and these specifications are based on the c. p. rating. Also our c. p. photometer is capable of more rapid use than the spheres.

The integrating sphere photometer for the measurement of light sources is based on the theory that with an interior white diffusing surface the brightness at any point of the sphere wall is proportional to the m. s. c . p. of the source of light within. This theory is strictly true for an ideal condition when no foreign body to the light source is present in the sphere. To measure the illumination on the sphere wall a small portion of it is removed and a test window of diffusing glass substituted. A photometer track is placed so that the light passing through the test window is balanced against that of a comparison lamp which has been calibrated with the sphere. It is necessary that none of the light from the test lamp shines directly upon the test window and this necessitates a screen being placed between the lamp and the window; see Fig. 2. This screen constitutes a foreign body and is a source of error. The lamp socket and other necessary fittings add to it. The screen divides the sphere into three areas; the first surrounding the test window receives only reflected light; the second forming the greater part of the sphere receives both direct and reflected light; and the third, opposite the test window, is entirely screened from it. The errors caused by this condition can be minimized by using a screen as small as possible and placing it so that the shaded areas are as small as possible. In spheres where the screen is small in diameter compared to the diameter of the sphere and the precautions stated are taken the errors are usually of negligible proportions. A sphere paint of very high reflection factor also tends to keep down errors.

The most effective safeguard against large errors is probably the use of the so-called substitution method of calibrating the sphere. This simply means having the standard lamps as near like the lamps to be tested as is convenient and placing them in the position during calibration that will later be occupied by the test lamps. In this way errors of the instrument are largely compensated for in the calibration. Each sphere has its own constant which is affected by the reflection factor of the surface and the size and location of the screen.

The measurement of the m. s. c. p. or the lumens of a lamp is a comparatively simple matter but when larger units such as reflectors or globes are measured, to determine the losses due to them, the conditions become more complicated

nd require a more intimate knowledge of sphere photometry, igs. 3 and 4. These show that more screens are necessary nd the sphere must be calibrated with all the apparatus, in- luding the test unit, in place, where it will be during the test, nd the standard lamp must be left there, extinguished, dur- ıg the measurement of the test unit. To measure the test nit the lamp to be used in it is measured in its normal posi- on but without the reflector or globe in place, the auxiliary is ut in place and another measurement made. The second will e smaller than the first by an amount equal to the loss



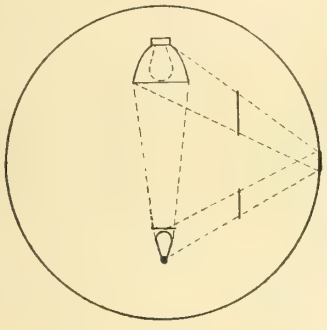


Fig. 3

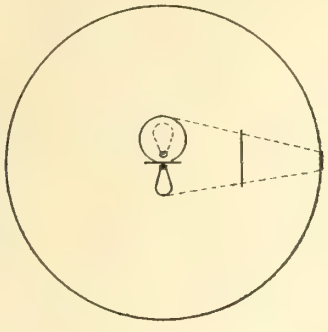

Fig. 4

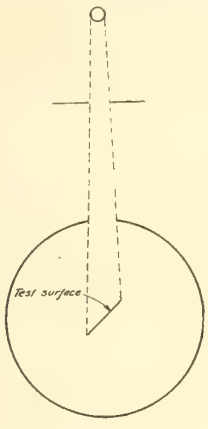

Fig. 5

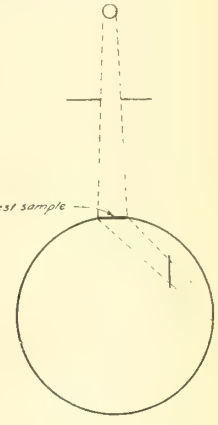

Fig. 6

aused by the reflector or globe. Globes for street lighting re sometimes purchased under specifications that place a imit on the absorption. This is very easily measured. Our arge sphere is provided with hinged trap doors in the top hrough which large units may be lowered and the opening losed up if desired. Or an arc lamp may be measured with he upper casing outside the sphere.

Illuminating engineers frequently need data on the re- lection factor of wall papers, paints and other surfaces that bsorb light. This is measured in a small sphere. A surface whose reflection factor has been determined must be used as a standard with which to calibrate the sphere.

A mirror or a surface of magnesium carbonate or other similar surface is suitable for use as standards. Standardizing such a surface is rather a long job, requiring the measurement of the reflection of a great many angles, Fig. 5. With a standard surface placed in the sphere and turned away from he test window a beam of light is directed into the opening at the top so that it falls on the standard. A measurement is hen made from which the flux of light entering the sphere is calculated. The standard surface is removed and the test surface put in its place. From a measurement with this the amount of light reflected from the sample is calculated.

The transmission of transparent and translucent materials is made by causing the light to shine through the opening in the top of the sphere and then measured, Fig. 6. This gives the value, which is 100 per cent., all of the light having passed through the clear opening. A sample placed over the opening will absorb and reflect some of this light, the re- mainder being measured and the result expressed as the per- centage of the light transmitted. If a sample so tested is of a diffusing characteristic it is necessary to state the charac- teristic of the beam of light because a concentrated beam will give a different result to a beam of diffused light. However, to test different samples the results can be compared if test- ed under similar conditions. Also if two sides of a sample are not similar the results may not be similar and a statement should be made as to which side is turned toward the light. This is shown by a test of ribbed window glass which trans- mits 90.3 per cent. with the opposite side out. Clear window glass transmits 87.3 per cent.; wavy wired glass clean trans- mits 75.2 per cent.; a dirty sample transmitted 38.4 per cent.

A person confronted with the task of selecting diffusing globes has to compromise between two opposing factors, transmission and diffusion. Both are highly desirable, yet one is obtained at the expense of the other although not necessarily to the same extent with different makes. The transmission is measured by the sphere photometer and the diffusion by a different means. There are different ways of expressing the degree of diffusion, but one in common use is to measure the distribution of brightness across the pro- jected area of the globe. If a globe has a lighted lamp inside it has the appearance of a disk and if the diffusion be perfect it will be uniformly bright all over its area, otherwise the center will appear brighter than the rest. If an opaque screen with an opening in the center is placed in front of the globe the candle power per square inch of the globe area exposed can be measured. This opening may be square inch area and should be fixed and the globe arranged so that it can be moved across the photometer track, measurements being made at convenient intervals. These results plotted in the form of a curve show the variation in brightness from the center to the edge. This method can also be used with flat samples of material.

Another very important use of photometry to illuminating engineering is the measuring of the distribution of light from various lighting units. There are many forms of photometers

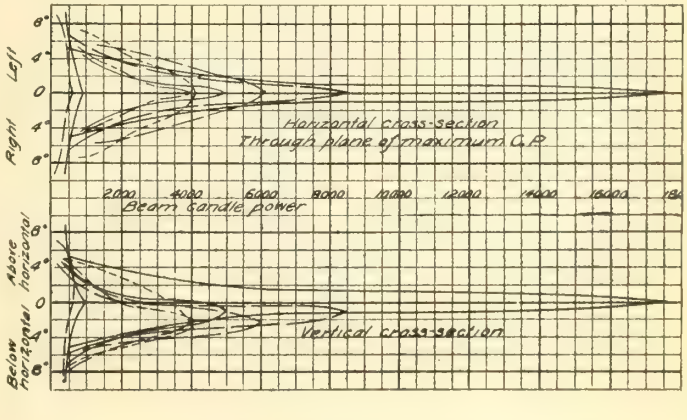

Fig. 7
Curves showing the horizontal and vertical cross-section of the beam from an automobile headlamp equipped with different types of glasses

for doing this but most of them make use of mirrors to direct the light from different angles from the units into the photometer axis. The one in use in this laboratory has two mirrors mounted at suitable angles on the one frame which can be rotated about the test unit so that candle power measurements can be made at different angles in the vertical plane. The distance from the light center of the unit to the photometric device is 10 feet, and the c. p. values are ex- pressed as apparent c. p. at 10 feet. The word apparent is used because the light from a large unit does not follow the

inverse square law at such a short distance. The 10 feet distance is commonly used in American laboratories.

In interpreting the results of tests the absorption of light by the mirrors must be taken into account. This may be done by calibrating the comparison lamp with the standard on the track and then in the distribution head and calculating the absorbtion from these results or by placing the standard directly in the distribution head and adjusting the voltage across the comparison lamp until a balance is obtained. The latter method requires a little less time. The most suitable method to use depends on whether a direct reading c. p. scale is used or the c. p. is obtained by reference to a table or by calculation.

It is common practise to make c. p. measurements at each 10 degrees around the unit. This method should not be blindly followed as some units change in c. p. so rapidly in some zones that very erratic results may be obtained. The curves in Fig. 9 show the effect of ¼ inch differences in the position of the light sources on the angle of the maximum c. p.

In summarizing the results of distribution tests the lumens in the principal zones are calculated for both the bare lamp and the lamp equipped.

Distribution tests of projector lamps have to be measured in a different way. A typical example is that of a series of tests on automobile head lamps we were called upon to make in connection with Ontario's head lamp law. A standard head lamp was set up so that it could be set to different angles in the horizontal and vertical planes and the beam was explored by means of an illumination photometer set up at the opposite end of the room. C. p. measurements were made at 0 deg., the center of the beam, 1 deg., 3 deg., 5 deg., 7 deg., 9 and 11 deg. from the vertical and horizontal axes Curves were plotted that show horizontal and vertical cross sections of the various beams, Fig. 7. To supplement these results the head lamp was set up on a table, fitted with castors, at the normal height from the road, (floor in this case) and the photometer was set up at a distance of 100 feet and the intervening distance marked off into 10 feet intervals. A reflecting test plate was used in this test and was placed on the floor and the photometer tube directed onto it. Foot candle measurements were made at each 10 feet mark by moving the head lamp up. These measurements gave the

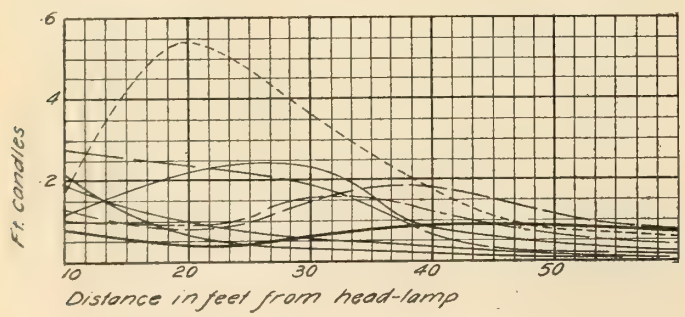

Fig. 8—Curves showing difference in road illumination from one automobile head lamp equipped with different types of glasses

road illumination from each lamp for the different glasses investigated. The curves serve as a check on the distribution curves, Fig. 8.

So far we have considered photometry in the laboratory. There is another very different branch that takes us out into streets, stores, offices, factories and anywhere where illumination is to be measured.

Of course work of this kind must be done with portable photometers. These photometers are usually built for a very wide range of work, such as measurements of c. p. in any direction, foot-candle and surface brightness. To make a survey of illumination the area selected should be representative of the conditions, as regards the surroundings, that prevail throughout the installation. The area is marked off into squares and a test station located at the center of each. In offices desk tops are 30 inches above the floor and measurements are usually made on this plane. In factories the bench height or machine height is the reference plane. Street lighting may be measured on the roadway or at some plane above it. There is no standardized method of making such surveys and much of the value of the test depends on the judgment of the one conducting it. Since the Commission started designing and installing street lighting our measurements have

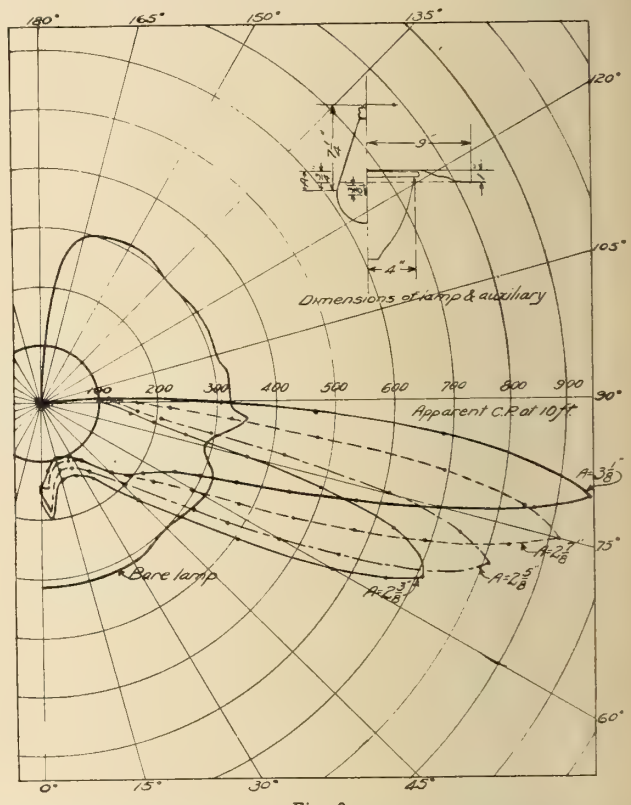

Fig. 9

Distribution curves of a gas-filled lamp equipped with a prismatic reflector. Different curves show the effect of different vertical positions of the lamp filament. An example of a case where a large number of candlepower measurements must be made to obtain the true distribution curve

been made on a plane 30 inches above the road. This has become a sort of standardized method with us to enable comparisons to be made. Sometimes vertical illuminations on an adjacent wall is required and in interiors the brightness of fixtures and the ceilings against which they are reviewed or the brightness of reflections from polished surfaces.

The Electric Club of Toronto

The regular Friday noon-day luncheons of the Electric Club of Toronto, were resumed Nov. 8 at the Prince George, the speaker being Mr. Alfred T. DeLury, Professor of Mathematics in the University of Toronto. Professor DeLury spoke on the subject, "On Keeping Step," enlarging upon the necessity of co-operation and a co-ordination of interests in the pursuit of any worthy end, just as the "tramp-tramp" of the soldier battalion is symbolic of the unified efficiency of the army. The speaker, however, warned against the possibility of carrying organizations and standardization to such an extreme as to crush individualism, and expressed the opinion that, in the end, more substantial progress would result by the free exercise of individual thought and free expression of that thought. As a teacher, he considered the most important function of his profession to be the training of men and women to think—to arouse in them the desire and curiosity to discover things and reach conclusions for themselves.

Hydro-Electric Reconstruction at Sherbrooke

The reconstruction work of the water power plants owned by the city of Sherbrooke, brought about interesting results, and a short review of the work done will show what can be accomplished in the way of raising the capacity of many an existing hydro-electric plant at a comparatively small outlay, and in some instances, as will be seen from this description, without interruption to plant operation.

The two corporation plants are situated on the Magog River. The Rock Forest plant is located at the outlet of Lake Magog, while the older plant of the two is located on Frontenac street, within the limits of the city of Sherbrooke. Both plants depend on the water storage of Lake Memphremagog, which is discharged at the rate of 550 cubic feet per second.

The total capacity of the two plants of the city of Sherbrooke, prior to reconstruction, was 2900 horsepower, as measured at the switchboard at the distributing point of the Frontenac Street station. The plants were rapidly approaching their ultimate capacity and the city of Sherbrooke decided to take steps to increase the capacity of these plants in order to enable them to cope with the demand from munition works.

A careful study was made of the hydro-electric equipment of the two power houses and tests were carried out to ascertain the performance of each machine, as well as the performance of each plant. With this information, the programme of reconstruction was laid out, aiming at the maximum amount of power obtainable under the highest possible commercial efficiency. The construction work was so planned as not to interfere with the operation of the plants except for one unit at a time.

In order to follow this work more readily, it will be well to give a brief description of the plants prior to the time of reconstruction.

Original Plant Equipment

The Rock Forest plant was built in 1911. This plant is some seven miles out of Sherbrooke. The power house equipment consists of two direct connected water-wheel generators of 940 kv.a. each, 3 phase, 60 cycle, 6,600 volt, operating at 180 r.p.m. The turbines are set in concrete open flumes. The maximum capacity of the two units under a head of 30 ft., was 2,200 h.p. at the Rock Forest switchboard. Two direct current water wheel driven generators of 50 kw. each are supplying excitation for the alternators.

The current of the Rock Forest plant is transmitted to the Frontenac Street plant, where it is stepped down to 2,200 volts for local distribution. The two power plants are operating in parallel.

The Frontenac street power house was built in 1908. It consisted of two direct connected water-wheel generators, of 25 kv.a. each, 3 phase, 60 cycle, 2,300 volt, operating at 225 r.p.m. The turbines were of horizontal type and were installed in steel cases. The combined maximum capacity of these units, under a head of 28 ft., was 1100 h.p. at the switchboard. A spare turbo-generator of 500 kw. was installed in the same plant, operating at 180 r.p.m. Two direct connected turbine driven exciters of 30 kw. each furnished the exciting current for the alternators.

The 6,600 volt transmission line connecting the plants consists of two 3-phase No. 1 B&S copper wire lines, carried on cedar poles and supported by Victor porcelain insulators No. 472.

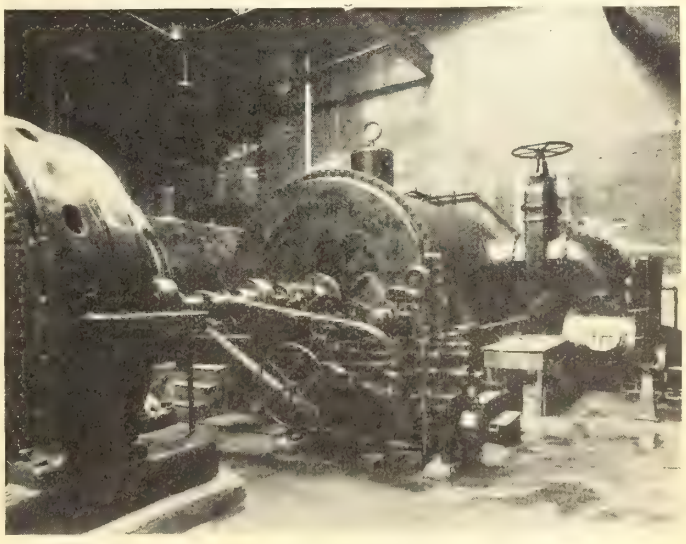
After an examination and tests of the entire equipment, the following were the conclusions arrived at.

1st. The Rock Forest turbines were inadequate in capacity and inefficient.

2nd. The transmission line losses were too high and the line drop excessive for satisfactory operation.

3rd. The turbines at the Frontenac Street plant were of old design and inefficient.

4th. The crib dam at the Frontenac Street plant was wasteful of water.



5th. The small turbines driving the exciters of the Frontenac Street plant were inefficient.

Reconstructed Plant.

While the Rock Forest plant was of modern design and construction, the maximum load the two units would develop at the switchboard at Rock Forest, was only 2,200 horsepower. In view of the local conditions not permitting of the realization of the full extent of power with the old turbines, it was decided to replace them in order to increase the capacity of this plant. As the Rock Forest plant has the advantage of the pondage of Lake Magog, which is approximately five square miles in area, the capacity of this plant was based on a load factor of 50 per cent.

The reconstructed units developed, under test, 3,000 horsepower at the switchboard, when operating jointly under a head of 30 feet. These turbines were furnished by the Morgan-Smith Company, of York, Pa.

The 940 kv.a. Canadian Westinghouse generators in this plant have done excellent service, when connected to the old turbines, and now with the considerably increased load, by the installation of the new turbines the same generators

Turbine and governor equipment, Frontenac St. Plant, Sherbrooke, Que.

carry the overloads under low power factor conditions in a most satisfactory manner.

The replacement of the twin, horizontal, centre discharge units was carried out in twenty days, with little inconvenience to power consumers, as by special arrangement enough water was discharged from Lake Memphemagog during this time, to permit of operating the spare 500 kw. generator at the Frontenac Street plant, which ordinarily would be out of service.

Attention was next given to the transmission line. The operating difficulties under a transmission voltage of 6,600 proved this voltage to be inadequate. The low power factor

at the load was responsible for an excessive drop, and at times the alternators were called upon to generate current at a voltage in excess of 8000. The investigation of the transmission line showed that a No. 472 Victor insulator was suitable for an operating voltage of 13,200.

The line is of triangular construction, with a spacing just sufficient to comply with standard requirements for 13,000 volts. It was found that the three Canadian Westinghouse, 533 kv.a. 6620-2200 volt transformers were built with standard 13,200 volt insulation, and could be operated with a grounded neutral. It was, therefore, decided that the current from the Rock Forest plant be transmitted at 13,200 volts and the installation of three step-up transformers at the Rock Forest plant was recommended.

With the installation of the three step-up transformers of 750 kv.a. each, at the Rock Forest plant, one line was placed in successful operation at 13,200 volts and the second line was operated at the lower voltage, pending the completion of work of reconstruction of a 6,600 volt substation of one of the power consumers, situated along the transmission line.

With both lines operating at the higher voltage, the saving in transmission will amount to 400 horsepower under the maximum conditions of power generated at the Rock Forest plant. Besides that, the voltage drop will be considerably minimized, thus resulting in an improvement in the power factor at the Rock Forest plant. The combined increase in power generated and transmitted over the two 13,200 volt. transmission lines, as measured at the switchboard at the receiving end of the Frontenac Street plant, is fully 50 per cent. over the power received at the distribution point before reconstruction.

The modifications to the plant at Frontenac street involved a considerable amount of work. As the city owned the right to develop 10 feet additional head on the Magog River, the new plans covered a 38 ft. development.

A concrete dam was built immediately downstream from the old crib dam. The dam is 285 feet long, with a maximum height from rock to stop log platform of 56 ft. The construction was carried on practically without interruption to the plant, except for a period of a few days. A great deal of concrete was placed in weather below zero with satisfactory results. To expedite the construction of the concrete dam, pneumatic placing of concrete was resorted to. The construction of the dam was carried out by Messrs. MacBean and Williams, of Montreal, and Mr. W. W. Plum was the contractor's engineer on the job.

As this plant is located between two privately owned plants without any pondage between them, a uniform flow of water is aimed at throughout the twenty-four hours a day. This restricted the capacity of the Frontenac Street plant. In order, however, to enable the plant to carry peak load fluctuations and to utilize occasional excess water, a load factor of approximately 70 per cent. was assumed, and the equipment was chosen on this basis.

The two old turbines developed, at full gate, when operating together, a maximum of 1,100 h.p. They were of an old type of construction, inefficient in the use of water and rather costly as to maintenance. As the steel cases and shafts were of liberal design, same were retained in order to permit of more rapid installation of the new units. The new units were supplied by the Boving Hydraulic & Engineering Company of Lindsay, Ont. The turbines are direct connected to 1,000 kv.a., 60 cycle, 3 phase, 2400 volt alternators, operating at 300 r.p.m. These machines are of Canadian General Electric make.

It was recommended, in view of the low power factor of the load, that the two 625 kv.a. generators of the old equipment be used after reconstruction as synchronous condensers for power factor correction.

The reconstruction of this plant proved very satisfactory. Tests of the two units, operating at the same time, show that they develop a maximum of 2500 h.p. at the switchboard, or 1400 h.p. more than the old plant developed with the same water. The increase is therefore, 127 per cent. in plant output. Minor modifications to a somewhat restricted tail race will allow of a further increase in the capacity of this plant. To permit the distribution switchboard to handle the increased load, the oil switches, current transformers, etc., were replaced with equipment of a larger rating. All instruments were recalibrated. Tirrill regulators were installed at both power houses to improve the voltage regulation of the system.

The excitation of the old units was furnished by means of 2 - 30 kv.a. turbine exciters. One of these turbines was taking the water from the steel case of the main unit, at a sacrifice of efficiency of the big turbine. In the new plant the excitation is furnished by 1 - 60 kw. generator, direct connected to an induction motor, with the result of a considerable improvement in the efficiency of the exciter set.

The work was carried out under the supervision of J. R. MacGregor, superintendent of plants, and E. Noel, superintendent of transmission and distribution. The concrete dam was designed by T. Tremblay, City Engineer, and the entire hydro-electric work was planned and executed under the direction of M. A. Sammett, consulting engineer, Montreal.

Pro Patria

Captain Chester William Halstead, M.C., of Ridgetown, Ont., was killed in action on October 10th last. Before enlisting, Mr. Halstead was manager at Ridgetown for the Bell Telephone Company. The official Gazette, in referring

The late Captain Halstead, M.C.

to his gallant work at Paschendale, which won him the Military Cross, said, "His utter disregard for machine-gun fire inspired his men greatly. He, with his platoon, captured 77 prisoners and two machine guns, the latter being brought into action at once against the enemy. After the captured position had been consolidated, he went forward some 200 yards, where he met an enemy staff officer, whom, on his refusal to surrender, he promptly killed. He gave a splendid example of courageous energy and dash."

The Dealer and Contractor

Are Contractor-Dealers Going to Stand Idly by and Watch the Hardware Stores and the Druggists Skim the Cream off the Electrical Milk Can?

A Provincial Hydro inspector dropped into a hardware store in his local town the other day and found the proprietor in conversation with a customer about a new fuse plug. The customer had blown a 10 ampere fuse and explained that this had happened a couple of times when his wife had connected up her iron. He didn't know the reason; there was no other load on his house at the same time.

"Oh," said the hardware man, "you need a larger fuse. This is 10—I'll give you a 20."

"Well, all right," replied the customer. I think there's a 30 on the other side though. Perhaps you'd better give me a 30 and make doubly sure."

"That's correct," said the hardware man. "We'll make sure with a 30."

And this is an age of "safety first"; at a time when rules and regulations covering installations, and the people making the installations, are supposed to have rendered the use of electricity fool-proof. The inspector naturally took occasion to "butt in," and explained to these two innocent babes that the trouble was doubtless due to a defective cord and that by increasing the size of the fuse they were merely adding to the chances for one more bad accident. As to rules and regulations governing the size of fuses to be used, the hardware man had never heard of them.

And this is no isolated case. Who is to blame that the merchandising of electrical goods of every sort has been, in effect, taken out of the hands of the electrical dealers and is handled very largely by hardware men, druggists, milliners and what not? The druggist's profession, for example, is safeguarded by law to prevent life hazards and yet these same people are allowed to handle equipment carrying as much hazard possibly as the average prescription, without the slightest protection to the public.

As long as the merchandising of electrical equipment is in the hands of uninformed retailers and salesmen, what is the use of making rules and regulations? All over the country these stores are the dumping ground for unapproved material, shoddy appliances of every sort that dishonor the whole class of labor-saving equipment to which they are supposed to belong and create a big life-hazard at the same time. Further, appliances of every sort and size are being sold for lamp socket connection.

Mr. Goodwin expressed himself as greatly disappointed with the number and type of electrical stores he found in Toronto. The same criticism holds to a greater or less degree, no doubt, all over the Dominion. Isn't the average contractor overlooking a golden opportunity? Think how well the two operations—wiring a home and then supplying that home with numerous electrical appliances—dovetail into one another. What home is there that, having cost $100 to wire, is not an immediate prospect for appliances totalling a much greater amount than this—electric fixtures, lamps, table lamps, iron, percolator, toaster, range, hot plate, vacuum cleaner, washing machine, and so on—and yet this large amount of business the contractor hands over to the hardware man with his compliments and the result is the hardware man makes a mess of the whole electrical business and muddles things up generally for the public, the inspection department, the contractors and the manufacturers.

The time has arrived when the merchandising of electrical appliances is as much a specialized business as is the sale of motors or transformers. Either the hardware man must inform himself of electrical matters or the contractor-dealers—who are already informed—must take it over. We must not forget that the hardware trade is well organized and is handled by men of intelligence who, if given half a chance will master the art of selling electrical goods. If contractor-dealers want to hold the field they must not delay very much longer.

The Establishing of Rigid Resale Prices Will Not Solve the Ills of the Electrical Industry—The Solution is Co-operation and Better Merchandising

A number of solutions have been offered for the difficulties besetting the path of the electrical contractor-dealer. The one most commonly mentioned is that manufacturers should establish resale prices on all the articles they make. This means that drastic measures would often have to be taken to enforce the maintenance of these prices, but contractor-dealers have frequently argued that manufacturers should refuse to sell to any dealer who did not hold to the price formally fixed on any article which he may carry in stock.

There can be no doubt that a measure of protection by the manufacturers and jobbers is due the dealer, but it does not appear that the arbitrary establishment of resale prices is the best form that protection can take. On the face of it, it is evident that one dealer can do business on a smaller profit than another and it constitutes an injustice, therefore, not only to the buying public, but to the dealers themselves, that the same fixed price should be charged in all localities and under all conditions. There is the other side of it, too, which we in Canada do not appear to have sufficiently considered, namely the legality of the proceeding. Can this practice be construed as a restraint of trade?

Right at the moment the whole matter is being thrashed out along this line in the United States courts. The Federal Trade Commission has just disposed of a case in which complaints were issued, charging violations of the law through fixing the resale price of articles, and an order to cease and desist from this practice has been issued in the case of Chester, Kent & Company, of Boston, manufacturers

of proprietary medicines. The order forbids the company to:

(a) Indicate to dealers the prices for which its proprietary or patent medicines shall be resold.

(b) Securing agreements from dealers to adhere to such prices.

(c) Refusing to sell to dealers who fail to adhere to such prices.

(d) Refusing to sell to dealers who fail to adhere to such prices upon the same terms as dealers who do so adhere.

(e) Furnishing any advantage to dealers who adhere to the resale prices, while refusing similar treatment to dealers who do not adhere to the prices.

This order of the Commission follows a similar decision of the Supreme Court of the United States in the case of the American Graphophone Company. The Federal Trade Commission has decided to issue complaints against all business concerns who refuse to sell unless the purchaser will agree to maintain a resale price fixed by the seller. It is claimed that when an article once passes from the maker to the purchaser, the latter owns it and may sell it at any price he chooses, so long as that price is not below cost, in which case he would be entering into unfair competition with other retailers selling the same article.

It is evident, therefore, that so far as the United States is concerned—and there is little doubt conditions are identical in Canada—the establishment of fixed resale prices will not solve the difficulty the contractor-dealer is meeting in the way of making a living profit. The solution lies rather in better merchandising methods, a closer study of the conditions under which each is operating and a better co-operation between the dealers themselves, first, and the manufacturers, jobbers and contractor-dealers, second. We are too apt to take it for granted that the cause of failure in business is too low a resale price. This is very rarely the case. Poor business methods in the retail business are almost universal, and this, we believe, is the direction along which education must proceed before the general condition of electrical merchandising, in Canada, is placed on a satisfactory and stable basis.

Those Who Pass and Those Who Pause—Which Kind of Window is Yours?

If there is any doubt in your mind as to whether it pays to spend a little time in making your windows attractive try this test yourself. Station someone outside your window with instructions to count the people who pass your store, and those who pass in front of your window. Then change the trim, making a special effort to produce an interesting display, and try the same plan.

Unless your experience is an exception you'll find that the well-planned, carefully trimmed window will attract a considerably higher percentage than the window jumbled together in a hurry some Monday morning. Care and thought in window trimming always pay.

You may learn some things about color and motion and arrangement from this single test that will help you in every window you trim.

But remember this when you look over the tally sheet of people who pass and people who pause: The figures are only an indication of the value of a trim as an effective sales factor.

Two windows, for example, might draw equal crowds, yet one would merely satisfy idle curiosity, while the other would actually sell goods. The important thing to remember is to put sales interest into the trim. The nearer you can bring your message home to the passer-by the more effective is the trim.

Don't forget that the window space is the most valuable part of your store. Make the most of it.

Change your trim often. Keep up with the times. Try to have the most attractive window, not only on your street, but in your whole city. Don't think for a minute that your chance is limited by the size of your window, for it isn't true. Small windows frequently are better trimmed than those which can show a half block of plate glass.

The effectiveness of your window depends solely upon the plan and its execution—and both depend on you.

Notice re Meter Loops

The Chief Inspector of the Toronto Hydro-electric System has asked the attention of electrical contractors to the need of allowing sufficient length on meter loops for power services. Each single wire should not be less than eighteen inches in length.

New Book

Central Station List—published by the McGraw-Hill Book Company, Inc., 10th Avenue and 36th Street, New York. This book contains a list of central stations in Canada and the United States by states, provinces and cities; statistics showing the total number of private and municipal plants, companies selling appliances, companies having day service, and other data; towns with a population under 1,000 getting current elsewhere; state and provincial commissions having jurisdiction over electric light and power utilities; index to central stations whose names do not indicate their location. Price $15.00.

Trade Publications

Condulets.—Suggestion No. 33, by the Crouse Hinds Company of Canada; describing an actual installation of weatherproof outlets and fittings.

C.G.E. Publications.—Bulletin 40021, describing belted direct-current generators, Type LF, and Bulletin 48940, describing constant energy arc welding sets for metallic electrodes—both well illustrated.

Switches.—Catalogue No. W-38, by the Square D Company; describing Square D switches of the steel-enclosed and iron-enclosed types; also motor starters, compensator type switches, plug receptacles, meter protective trims and accessories; illustrated.

It is to be hoped that dealers in electrical equipment will not fall behind in the movement evidenced in the other lines of retailing to get the Christmas shopping campaign well under way during the present month. The average citizen has caught the spirit of conservation underlying this programme and is doing his shopping a month or six weeks earlier than usual. If the electrical dealer delays his advertising propaganda, he will undoubtedly lose the trade which the excellence and utilitarianism of his produce justifies him to expect in this holiday season. The Christmas stock should be displayed at once, windows dressed with holiday goods and the spirit of Christmas injected into the advertising, so that people may know that electrical stores are alive to the newer conditions under which we are now living.

3-Wire D-5 Meters

At the present time when great attention is being given to conservation and standardization, the new direct current, 3-wire, service watt-hour meter just placed on the market by the Sangamo Electric Company is attracting attention. This meter consists simply of two standard 2-wire elements placed side by side in a common base and registering their kw.h. on a common recording train so that the sum of the revolutions of the two elements will be properly added and indicated on the kw.h. dial of the meter. This is effected by means of a very simple but ingenious differential gearing within the recording train so that no matter what load there may be on one element as compared with the other, the total revolutions of the two elements will be accurately added and recorded. Even with one element fully loaded and the other one without load, the registration is as accurate as though each element were recording on a separate train. This arrangement of meter elements and train is not new, but has been given a thorough and successful test on similar ampere-hour meters built for use with storage batteries on submarine vessels of the U. S. Navy, during the past two years. The only difference between these very successful ampere-hour meters for submarines and the present 3-wire D-5 service type meter, is in the fact that the driving elements in the ampere-hour meters have permanent magnet fields instead of shunt energized fields of the watt-hour meter.

As will be seen from Fig. 2, each element of the new 3-wire meter is a standard 2-wire element including the light

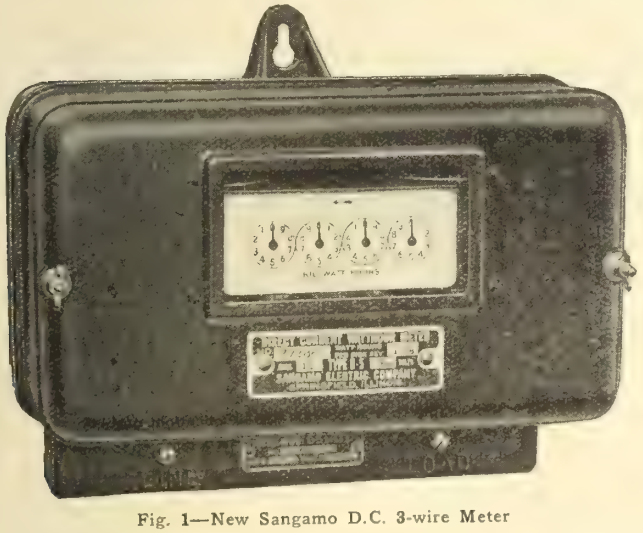


Fig. 1—New Sangamo D.C. 3-wire Meter

load adjustment, the arrangement of damping magnates, and in the case of meters over 10 amperes capacity, the arrangement of internal or external shunts. As shown in diagram Fig. 3 and from the arrangements of the elements it will be apparent that this meter achieves the requirements of a true 3-wire direct current meter; that is, one which will measure and record accurately the load on either side of a 3-wire distributing system, no matter whether the other side is entirely dead. For example, if the fuse in one outer line of the system is blown or purposely withdrawn, the element connected in the other side will record accurately the load on that side, as its potential circuit and measuring circuits are independent of the side which is open. If the neutral fuse is blown or withdrawn, the two potential elements remain in series across the outer lines so that the meter will continue to record any load that may pass through it between the outer wires with the neutral open. Under widely unbalanced conditions of voltage between the outer lines, this meter will record with a degree of accuracy which it is claimed is impossible with any former 3-wire direct current meter having a single potential element connected either between one outer line and the neutral, or between the two outer wires. As shown in the diagram, the elements are so connected through an interchange of connections within the terminal box itself that the load wires, from and to the line, pass in and out of

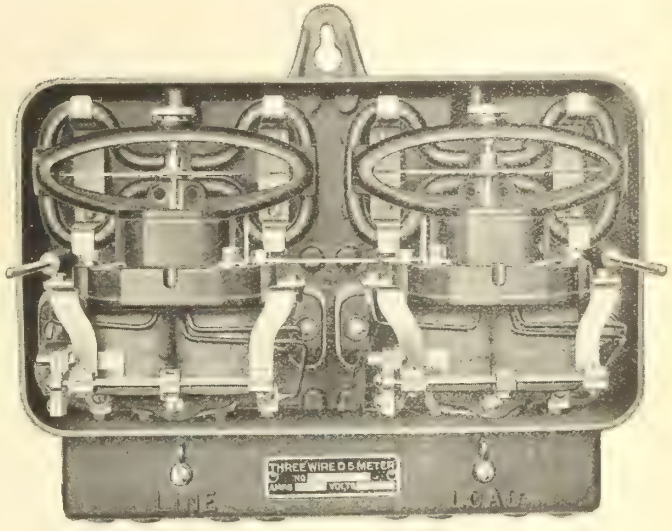

Fig. 2—Meter with case and recording train removed, showing two independent standard 2-wire motor elements

the meter in regular succession; no crossing over of interchanging of leads being required. The recording train is held on a bracket connecting the two motor elements, shown in Fig. 2 with the train removed, and absolutely correct meshing of the two worm wheels on the train, engaging with the two elements, is obtained by a system of locating rear bearings of the worm wheels similar to that used in the standard 2-wire meter. The train is held in position by a

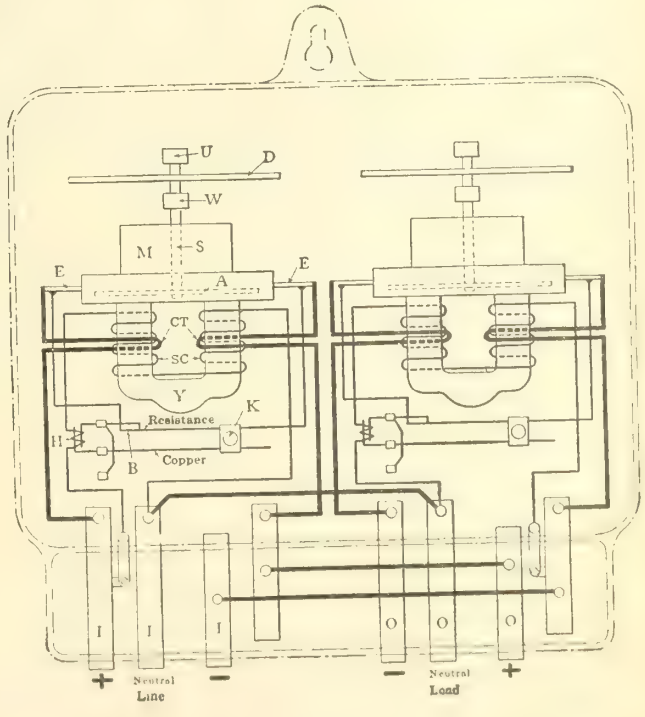

Fig. 3—Wiring diagram showing internal connections of the new Sangamo 3-wire D.C. Meter

simple device operated from the top front so that it may be readily removed for purpose of inspection and calibration of the elements. In calibrating, each element is considered and tested as a standard 2-wire meter without respect to the other element. For this reason, an absolutely perfect balance of

the two elements may be secured in minimum time and effort by the tester.

The meter when connected, occupies about the same space on the wall as an ordinary polyphase service type alternating current meter. This meter will be supplied in all capacities from the unshunted 10 ampere meter, to the largest externally shunted capacities.

The Walger Insulated Wire Connector

The Walger insulated wire connector is illustrated herewith. This is a device for fixture outlets and motor leads, which does away with blow torch, alcohol, acid, solder, rubber tape and paste, and allows the operation of making connections with a considerable economy in time. All you require to make the connection secure is a screwdriver. It is argued by the manufacturers of this device that an electrician can leave the workshop with enough connectors in his pocket to wire up the fixtures of a whole house; that he can do the work in a fifth the time, and always have clean hands to

The Connector

handle the fixtures; that the device facilitates the exchange of fixtures and that it can be used without difficulty in places where the electrician is cramped for room. It is also claimed that a piece of work on which these connectors have been used exclusively can be examined by the inspector more readily and more thoroughly and that as a result the many fires attributed to defective wiring may be greatly reduced by their use. The illustrations show the method of making

The Insulating Shell

the connection and also the insulating shell and cap that covers each connector. The device is approved by the Underwriters' Laboratories, of Chicago, and by the Hydro-electric Power Commission of Ontario. It is being handled by Mr. C. Jackson, 22 College Street, Toronto.

Personals

Mr. John S. MacLean, advertising manager of the Canadian General Electric Company, and also of the Canadian Allis-Chalmers Company, for the past five years, has resigned.

Lieut. M. B. Hastings, secretary, A. H. Winter-Joyner, Limited, Toronto, has been awarded the Military Cross. Lieut. Hastings left Canada with the 4th Canadian Mounted Rifles Batallion, but was later transferred to an artillery company.

Obituary

In our last issue we recorded the appointment of Mr. H. E. Randall, of the Shawinigan Water and Power Company as sales agent of the Ludlum Electric Furnace Corporation, N.Y., and his serious illness from influenza. We regret to report that the illness terminated fatally, the electrical profession thus losing one of its younger and most promising members. Consequent on Mr. Randall's death, Mr. R. J. Beaumont has been appointed manager of subsidiary companies, and Mr. P. R. Labelle power sales manager of the Shawinigan Water & Power Company.

Current News and Notes

Estevan, Sask.

A proposal is on foot to build a plant at Estevan, Sask., for the supply of light and power to the cities of Weyburn, Regina, Moose Jaw and intervening points. It is believed that such a plant could be made a commercial success by the use of lignite fuel. Reports state that local opinion is decidedly in favor and that steps will be taken immediately to secure the necessary funds.

Eyebrow, Sask.

Messrs. Carlyle & Seeley, of Eyebrow, Sask., are planning the installation of an electric lighting plant to light the business section of the town. While the matter has not been definitely decided, it is thought the plant will be designed for 15 kw., 110 volt, direct current operation, the motive power to be a 30 h.p. oil engine.

London, Ont.

Manufacturers in London, Ont., have been asked to run their factories on daylight saving time during the winter as a measure of combatting the power shortage.

The London Hydro-electric System completed the first ten months of the fiscal year with a surplus of $68,000 over all operating and capital costs.

Moose Jaw, Sask.

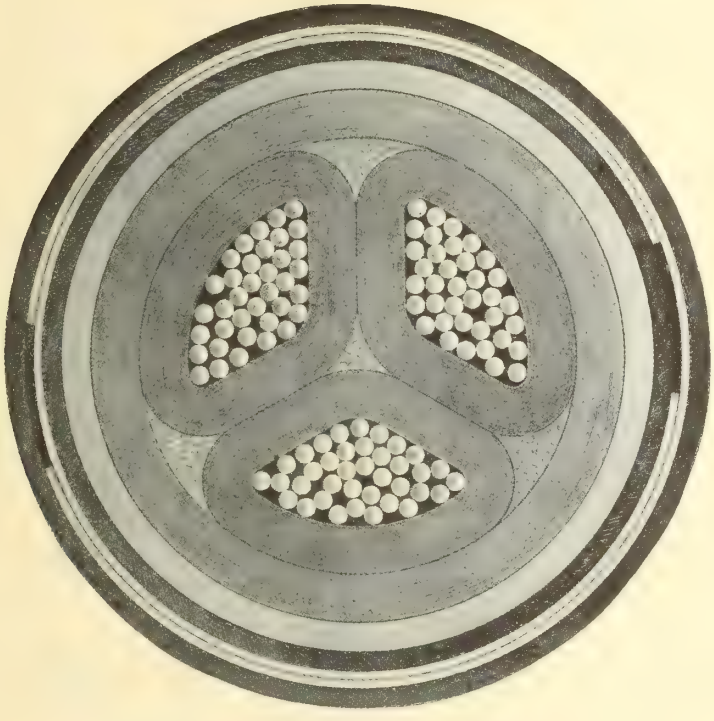
High operating costs are said to have brought about a crisis in the affairs of the Moose Jaw Street Railway, a privately owned system. Unless some immediate relief is forthcoming it may be necessary for the company to cease operating.

Quebec, Que.

Quebec city authorities have joined in the movement to protest against the increased rates announced by the Bell Telephone Company.

Regina, Sask.

The recent increase to the straight five-cent fare on the Regina Street Railway is, according to a recent statement, responsible for an increase of $20,000 in revenue for the first ten months of the year. Approximately the same number of passengers were carried.



Toronto, Ont.

In a report recently submitted by auditors appointed to go over the books of the Ontario Hydro-electric Commission, it is shown that the total assets of the Commission amount to $28,950,803. Under this heading is included an asset of $15,070,307, representing the value of the Niagara system and the seven secondary systems in the province. On the other side of the ledger are cash advances by the province amounting to $17,037,074 on the various systems; $1,200,000 on Niagara power development; $583,131, due Central Ontario System; debentures re purchase of Ontario Power Company, $7,984,000. Other debentures total $51,216; accounts payable $27,443. The liabilities also include reserves for sinking fund aggregating $238,531, and reserves for renewals contributed by municipalities and in respect of service and office buildings amounting to $1,139,258. There is a reserve of $137,701 for contingencies and the Commission owes to municipalities in respect of operating surpluses, $446,484. Another surplus is $83,509 arising from departmental operations in the service building. An insurance reserve of $2,451 completes the liabilities.

Wapella, Sask.

Mr. W. P. MacDonald, of Wapella, Sask., is planning the installation of an electric lighting plant and is calling tenders for a dynamo, engine, wire and general equipment.

FOR SALE

[illegible] alternators, from 25 KW to 900 KW, 25 and 60 cycles. Located in Canada.

CHARLES J. EACOCK,
107 Duke Street, Toronto.
[illegible] 3227 21-22

Alternator Wanted

250 to 350 KVA alternator, 2300 volts, 3 phase, [illegible] cycles, revolving field, 2 bearing, for direct [illegible] to water wheel; speed from 200 to 300 R.P.M. Apply Box 806, Electrical News, [illegible] Ont. 21-22

Transformers

FOR IMMEDIATE DELIVERY

25 Cycle Single Phase

5	300	KVA	2200 to 575	Volts.
3	50	KVA	2200 to 550	Volts.
3	40	KVA	2200 to 550	Volts.
6	7½	KVA	2200 to 550	Volts.
2—	15	KVA.	2200 to 220/110	Volts.
3—	7½	KVA.	2200 to 220/110	Volts.
4—	5	KVA.	2200 to 220/110	Volts.
2—	3	KVA.	2200 to 220/110	Volts.
1—	2	KVA.	2200 to 220/110	Volts.

These transformers were built by The Canadian Crocker-Wheeler Co., Ltd., and are in first class condition, some of them never having been used. They were bought before prices advanced so can be disposed of at attractive prices.

O'BRIEN & DOHENY,
Thorold, Ontario.
22-22

An electric pumping installation, completed about June 1, at Sidd's Landing on the Sacramento river, in California, made practicable the irrigation of 23,000 acres of rice land during the past season, the value of the product this year being estimated at $4,300,000. The product is that of the Provident Irrigation District, which spent $750,000 on its pumping plant and system of irrigating canals. This body of land, formerly considered worth $30 per acre, is now valued at $150 per acre.

The pumping equipment consits of four General Electric 500-hp., 2200-volt motors, direct-connected by flexible couplings to four Byron Jackson 42-in. horizontally split, double-suction pumps of a combined capacity of 220,000 g.p.m., against a head of 30 ft. Electric energy is supplied by the Northern California Power Co. The power required in pumping water for the tract of 23,000 acres cost about $35,000 for the irrigating season of five months.

The U. S. Council of National Defense makes this statement in a circular letter sent to the several State Councils of Defense:

"Housing and war work are vitally connected. A man who raises crops, turns shells, or builds ships must have a place in which to live. His health and efficiency are directly dependent upon housing conditions. Adequate and satisfactory housing is thus one of the outstanding needs of the day."

Walger Insulated Wire Connector

Solderless Connection

Insulating Shell and Cap

Patented Canada 1917.
Patent Pending U. S.

DISCARD THAT BLOW TORCH

Just think—no blow torch to explode or blazing alcohol to boil over, no injury to canopy or ceiling on account of smoke, no setting fire to wall covering, etc. with blow torch, no dropping of hot solder, burnt matches, bits of tape or soldering acid, paint work or walls not marred by dirty hands, no tools to fall from ladder, no time wasted going from one fixture to another, one trip up the ladder is sufficient.

All you require to make the connection secure is a screwdriver.

The Walger Insulated Connector is so simple in construction that it is impossible to make a mistake in making a connection. In other words, it is wonderfully simple and simply wonderful when you see it in use.

The Walger Insulated Connector is one of the most profitable electrical accessories you can handle. Write for further information.

Friends of the Electrician

"ANTI-SULPHURIC" ENAMEL
The only reliable protection against the action of acid and chemical fumes.

"FERRODOR"
Rustproof elastic paint. Superior to Graphite or Red Lead. Defies all climatic conditions.

"DRIOROL"
Oil-proof Enamel. Dries quickly over greasy and oily surfaces. Not affected by lubricating or transformer oils.

"ARMOUR"
Fire-resisting paint, or colorless solution.

"ARMACELL"
Possesses the highest insulating qualities of any varnish on the market.

"OHMALINE"
Black, quick air-drying insulating composition. Also supplied for stoving, and as a solid insulating compound.

"SHAYDOLITE"
for coloring electric lamps. Used in the Royal Navy. Weatherproof. Dries rapidly.

"ARMABRON"
Bitumen protective paint, elastic, acid-resisting, weatherproof.

DOSSERT CONNECTORS

The Superintendent of one of the largest electrical contracting firms writes us:
"The workmen have formed the habit of using Dossert Connectors for all kinds of connections and consider it a hardship if they are called upon to perform the tedious and laborious task of making a soldered joint with its attendant acid fumes, gasoline torch smoke and burned fingers."

Ask the man who makes the joint!

THE Industrial Executive, Foreman or Worker who, in this great National crisis, persists in ignoring any source of accidents, is morally guilty of treason to the Great Cause.

The success of our armies depends on maximum industrial production. The elimination of accidents is a powerful factor in production. And accidents cannot be avoided so long as open knife switches are used. If those in your plant have not been replaced with Square D Switches, why not? Ask your Electrician.

SQUARE D SWITCHES
do not hinder production

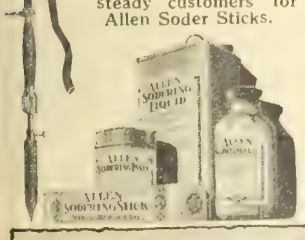
ECONOMY
RENEWABLE
FUSES

protect millions of circuits and billions of dollars worth of property in thousands of plants representing every branch of industry.

They are used by the U. S. Navy, leading powder and munitions plants, ship yards, steel mills and others who put accuracy and safety before anything else.

They cut annual fuse maintenance costs 80 per cent., because an inexpensive little "Drop Out" Renewal Link restores a blown Economy Fuse to its original efficiency.



No special tools or experience needed to replace the link and renew the fuse. Anyone can do it in a jiffy.

Order from your Jobber. Ask for Catalog 20.

WRITE FOR INFORMATION

LINCOLN MOTORS

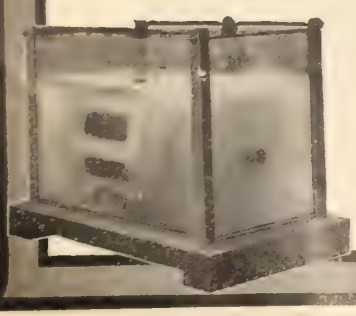
NOTICE

To Manufacturers and Others

We are not only builders of the famous Lincoln Arc Welder, but we are also in a position to quote you on welding and repairs to your machinery or boilers. We have complete equipment for this work and can have our plant brought to the job on short notice.

We keep a staff of operators ready for any emergency.

Let us quote you on your welding and save many dollars on machines that you would otherwise scrap. A phone call will bring a man in a hurry.



You can save 50 per cent.—very often more—by doing your boiler plate work with a Lincoln Arc Welder instead of rivetting it.

Lincoln-welded joints are 100 per cent. strong—rivetted joints are no stronger than the rivets themselves.

It has been adopted by boiler shops, structural steel works, street car and railroad companies as being the most practical solution of the present labor shortage.

A Lost Opportunity

As a wiring contractor, how many times have you turned down orders to repair the Motors or dynamos of your customers and let them send their work to the maker?

How much have YOU lost in prestige through not being able to take care of your customers' business?

How much have YOU lost in Profit on this business?

Get the habit of handling these repairs. Send them to a **Specialist in Repairs.** Don't send them to the maker. Your customer can do that, and he's already sick of it. The service is too slow. He wants quick work and an **absolutely reliable job.** You can give it to him.

Make up your mind now. Say "I'm going to get something out of the next repair job in this town."

You have the work of taking out and re-installing the machine **(Profit).** Send us the machine or part with a description of its action or symptom. We'll rush it through for you, give you an A1 job and you come in again on the **Trade Discount (More Profit).**

Others are doing it. Why not you? Write about it.

The Largest Storage Battery *Amperehour Meter*-Controlled

The Detroit Edison Company has for "Stand-By" Service the largest storage battery in the country. It consists of 150 cells each containing 163 plates, and has a capacity of 25,200 amperes at 110 volts (nominal) for one hour, and 80,000 amperes for ten minutes at slightly reduced voltage. The battery control panels are equipped with

SANGAMO

Ampere-Hour Meters

Let us tell you of others of the thousands of Amperehour Meters in daily use in central stations and isolated lighting plants, in car lighting, electric vehicles, wireless apparatus, and on war vessels and submarines of United States and allied countries. Ask for Bulletin 45 giving complete details.

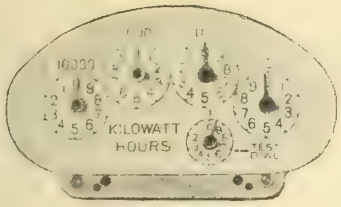
Best Known Cable Reel In Canada

NORTHERN ELECTRIC COMPANY

THE demand for Northern Electric products and the fact that they are made by the largest manufacturers of bare and insulated wires and cables for electrical distribution is a positive assurance of quality.

They are as near perfection in both dependability and durability as experience, workmanship and superior materials, combined with the most modern machinery, can make them.

Bare copper, rubber covered and paper insulated, lead covered cables of Northern Electric manufacture—are designed by the most capable engineering skill and tested to ensure safety and efficiency to the fullest degree possible.



Our nearest House will be pleased to submit specifications and prices upon request.

How Long Does It Take You ?

When you have to change the Potential or Current Coils on your Service Meters, if you are using the Sangamo Product note these advantages:—

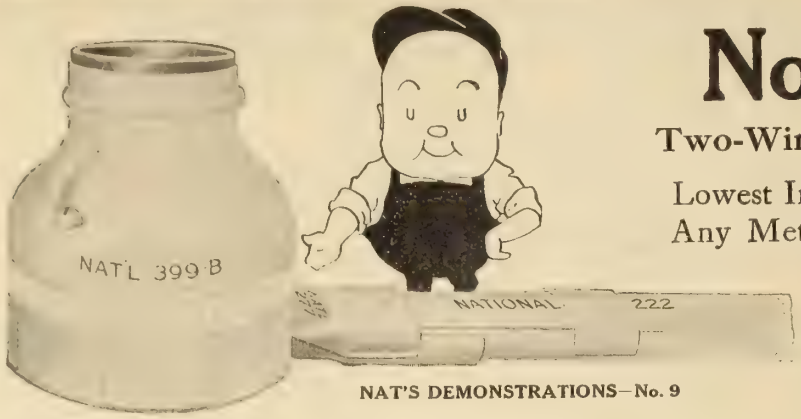
(1) The moving element is not dismantled.

(2) The new potential coil built on the core is replaced as a unit.

(3) Current Coils can be changed in a few seconds.

(4) The Air Gap does not change as all parts are dowelled.

(5) Simplicity and thoroughness of design makes faulty assembly an impossibility.



Write our nearest house for particulars and prices.

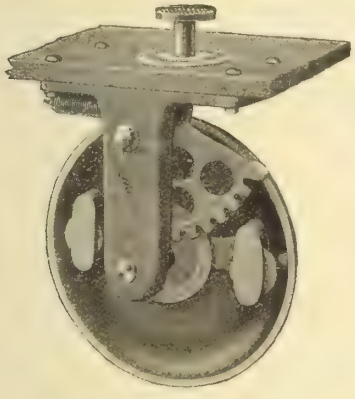
We urge you to use these famous, "better service" Keystone Car Specialties

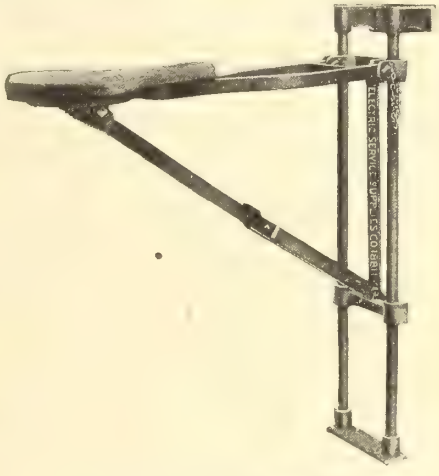


Faraday Car Signal Systems

Operates from line voltage—no batteries. Faraday Push Buttons, Buzzers and Resistances furnish an ideal, failure-proof car signal system.

Illuminated Car Signs

With these signs destination names can easily be changed and cars rerouted. Well labeled cars make more money.



Keystone Rotary Gongs

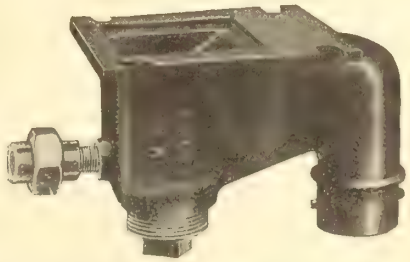
A louder gong and more continuous to meet requirements resulting from modern, heavy, noisy traffic in cities.

Safety Car Lighting Fixtures

To light your cars scientifically, efficiently and safely. To save you money.

Keystone Motorman' Seats

For the motorman or conductor. A real collapsible, safe and durable seat. They make operators more contented.



"Golden Glow" Headlights

To light up a path to safety for your cars. Only their famous reflectors can project the distinctive "Golden Glow" light.

Keystone Trolley Catchers

To protect your overhead construction from "flying" poles thus preventing delays and tie-ups.

Keystone Air Sanders and Valves

To automatically sand your tracks by compressed air. A real device for safety and accident prevention.

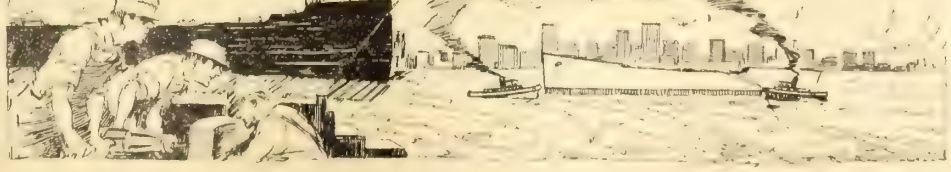
The Needs of the Empire

NEVER BEFORE in the history of Canada has greater opportunity been offered her Sons and Daughters to render SERVICE to the Empire;—and

NEVER BEFORE have the needs of the Empire demanded as high a standard of QUALITY in thought, deed and product as at present.

HOW NOBLY CANADA has responded is now known around the World and history will record it for the future.



THE PRODUCTS OF OUR MILLS are at the Fronts and on the Seas, in the Shipyards and Factories and in the Fields, faithfully fulfilling their mission of reliable performance wherever the Government's War-Winning Programme directs, as we are, and have been, stripped for action since the first call to arms.

THE NEEDS OF THE EMPIRE are many and the War-Winning Programme changes as necessity demands; but it matters not, the needs of the Empire are paramount and must be supplied.

THEREFORE, if in these trying times, we do not deliver promptly to you such of the products of our Mills or Blast Furnaces as you may need, console yourself with the thought that through us, you are rendering Service to the Empire and to the Cause that matters most for the Liberty, Justice and Freedom of the World.

THE "TYPE S" PORTABLE WHEATSTONE BRIDGE

Useful in the Shop and Laboratory for the Measurement of Resistance Adapted for Fault Locations in Telegraph and Telephone Lines and Cables.

The Type S Bridge is a thoroughly practical instrument for shop and field use. Being complete in every detail it is ready at all times for immediate use. It is easily portable, its weight being but 8 pounds. The precision of adjustment of its coils (Rheostat 1/10 per cent., Ratio 1/20 per cent.) insures accurate measurements. The galvanometer, the weakest element of such an instrument, is unusually rugged. It is a separate element and may be removed for examination or repair by taking out two screws. The battery is of the ordinary "flash light" type, and renewals may be procured practically everywhere. The price is $66.25 net, f.o.b. Philadelphia, boxed for shipment.

Bulletin No. 530 describes this instrument.

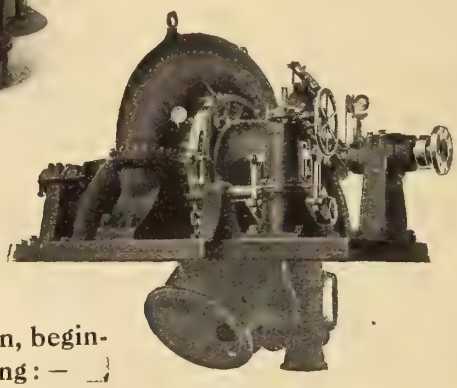
Save Coal and Aid Reconstruction

by an Efficient Development of

WATER POWER

and incidentally, bear in mind,

NO MATTER WHAT YOUR REQUIREMENTS



There's a "Smith" Turbine

TO FILL THE BILL.

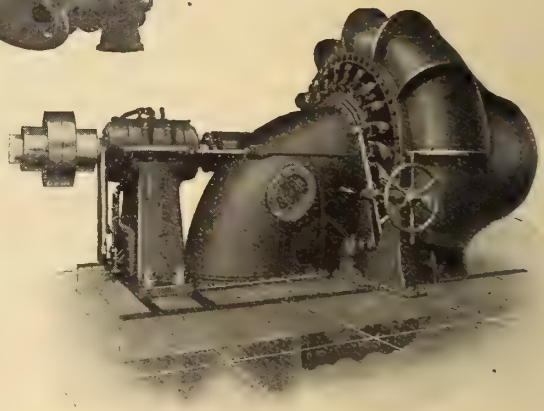
Of course they cost more than ordinary turbines, but you have the satisfaction of an

ABSOLUTELY DEPENDABLE HYDRAULIC TURBINE

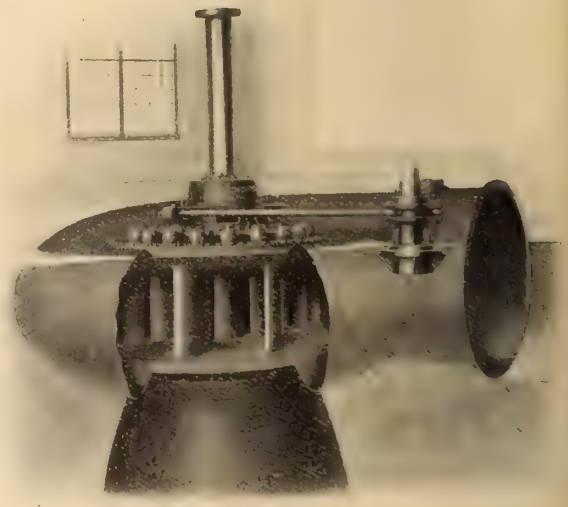
of Maximum Efficiency and Minimum Up-Keep

Look at the Turbines Illustrated and draw your own conclusions

These illustrations, in the order shown, beginning at the top, represent the following: —



1st.—Single horizontal scroll case unit, direct connected to generator. Two units furnished Buga Electric Co., Colombia, South America, each developing 275 horse power, 900 R.P.M., under 170 feet head.



2nd.—Single Vertical Shaft Wicket Gate Turbine, for open flume installation, and direct connection to vertical shaft generator. Two units furnished Electro-Metallurgical Co. of Niagara Falls, for installation in their Glen Ferris, West Virginia plant; each developing 2000 horse power, 100 R.P.M., under 26 feet head.

3rd.—Pair of Horizontal Shaft Smith "Francis" Turbines, mounted on cast iron scroll case; furnished San Joaquin Light & Power Co., Fresno, California; developing 5300 horse power, 450 R.P.M., under 210 feet head.

4th.—Single Special Horizontal Shaft Wicket Gate Turbine, for direct connection to Pulp Grinders. Two units furnished Chicoutimi Pulp Co., for installation in their Ouiatchouan Falls Mill, each developing 1800 horse power, 250 R.P.M., under 230 feet head.

5th.—Single Vertical Shaft Wicket Gate Turbine, enclosed in Plate Steel Scroll Case, with all gate operating mechanism on the outside. This unit furnished Kimberly & Clark Co., Neenah, Wisconsin, for installation in their Niagara Mill; develops 3,000 horse power, 240 R.P.M. under 60 feet head.

If interested in water power, write Dept. "N" for bulletins.

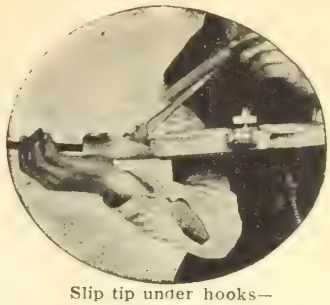
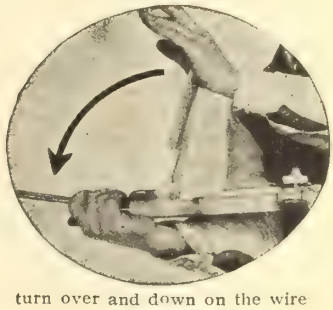
O-B Type E. Frog



TIME and LABOR SAVING with O-B TROLLEY FROGS

Installation of O-B Frogs is exceedingly simple. The trolley wires are gripped in a single powerful clamp. The Cam Tips are put on as shown in the illustrations at the right. That's all there is to do.



The Cam Tips absorb the first shocks of the wheel and provide a smooth passage from wire to pan. They take the brunt of the wear and may be renewed easily.

Polar Cub HOME MOTORS

The Demand for popular priced Electrical Home Devices has become quite general—Make an asset of this.

SEWING MACHINE MOTOR

Complete outfit for operating sewing machine includes Polar Cub Home Motor, rheostat, cords and plug and sewing machine attachment.

There is an extremely big demand for an item of this kind. Packed in substantial carton with attractive label.

Can also be used with all other Polar Cub Home Motor Attachments. **Retail price $15.50.**

Separate Vibrator Churner and Mixer Polisher and Grinder and Fan Attachments Retail at $1.50 Each.

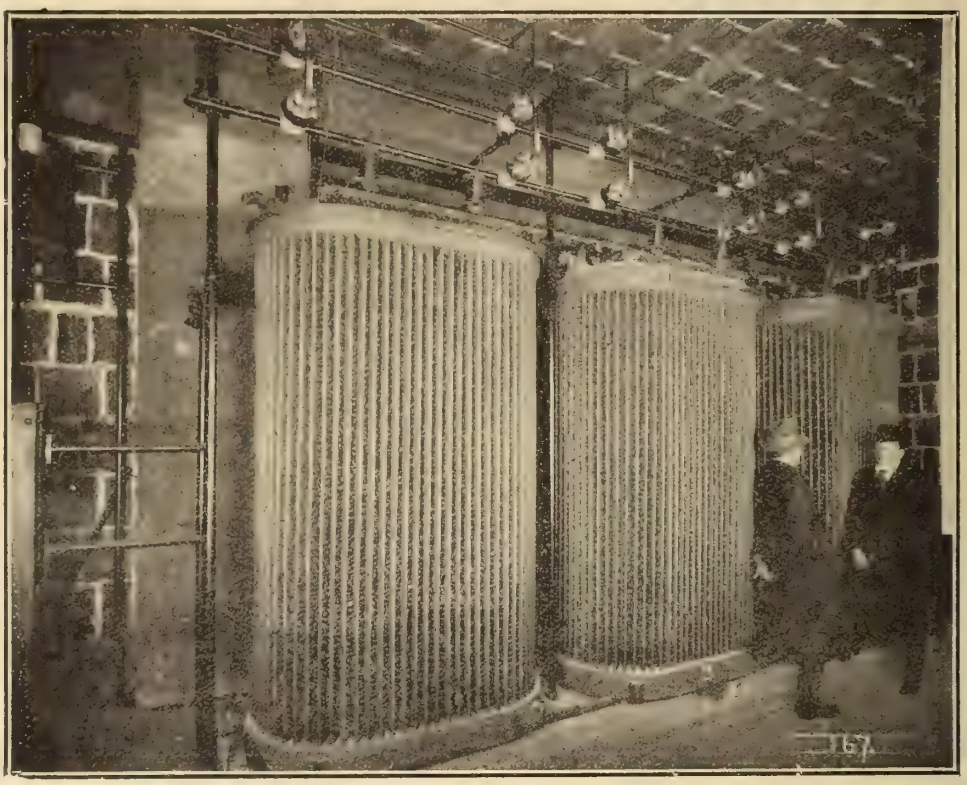
Can be used with the Sewing Machine Motor.

You can get complete units of any of the above.

Retail $15.50

DELUXE CABINET

Polar Cub DeLuxe Cabinet contains complete Polar Cub Home Motor with all Attachments. Includes Home Motor, Base, Rheostat, cords and plug. Churn and Mixer Attachment, Polisher and Grinder Attachment and Fan Attachment.



All in stained hardwood cabinet lined with silk and makes a very handsome set. **Retail price $25.20.**

The Sewing Motor is a good Xmas Gift—The Deluxe Cabinet is a Grand Gift

Production Records Which Make Sales For the Motor Distributor

When the production Manager and Factory Superintendent see production climbing to new records month after month, they are not unmindful of the part equipment reliability plays in helping reach the new records. Reliability in the motors which drive the factory machinery has a greater significance to them than to the man who signs the orders.

When equipment makes good on a production basis, the man who sold it can count on the active co-operation of the factory executives when additional equipment is required.

The regularity with which R & M Motors are specified on repeat orders wherever they have been introduced, reflects the good will of the factory executives—the men who are in the best position to judge their service records. And good will which extends beyond the purchasing department out into the shops is a sales asset of immeasurable value to the motor distributor, a dependable guarantee of a permanent, growing motor business.

Vol. 27 Toronto, December 1, 1918 No. 23

Are Hardware Stores the Best Medium for Distributing Electrical Appliances?

In recent issues we have referred a number of times to the conditions under which electrical devices are being retailed—amounting almost to a monopoly of the business, in many centres, by the hardware trade. Is this a desirable condition? Is it in the best interests of either the manufacturer, the jobber, the contractor-dealer, the central station or the public?

Strangely enough, the hardware dealers appear to have taken it for granted that they are the logical medium through which electrical merchandise must reach the public. For example, in a recent issue of a hardware trade journal a number of "kicks" are registered because in certain cases the electric stores in the locality presume to sell at a lower price than the hardware men think proper. Perhaps the conscience of the electrical dealer is not yet sufficiently elastic to allow him to charge profits which appear quite right to the hardware man, or it may be that there are other reasons. Is it not reasonable that the merchandising of up-to-date electrical goods, representing a quick turnover, ought to be done at a lower profit and that when the hardware man places these goods on the same basis as his own stock, often representing a big percentage of junk, he is treating the electrical business unfairly and actually retarding its progress. The article in question speaks of central station price-cutting, but it seems highly improbable under the power shortage conditions of the past few months that any central station will throw money away to create a condition of greater demand that they do not want.

The fact seems to be that hardware stores are not the **logical** channels through which we should distribute electrical goods to the public. Manufacturers and jobbers have placed their goods with hardware stores simply because this arrangement offered an opportunity of widening the market. They did not stop to consider the after effects of placing their goods in inexperienced and unsympathetic hands and the result has undoubtedly been, in many cases, dissatisfied customers and discredited merchandise.

Of course, it is one thing to say there ought to be enough electrical stores to take care of this business and quite another thing to get them going. It is doubtless evident to the contractors, too, that a fine line of profitable business is going to waste for want of proper taking care of. But, after all, the trouble seems to be that the contractor, pure and simple, knows little about retailing, which to-day has become something of a science. He is not interested in getting behind the counter and selling. As opposed to this the hardware trade has the selling organization all ready.

If one may sum up the situation, it appears to be a matter of choice between two conditions, neither of which offers an immediate solution. If the merchandising of electrical goods is to be placed in the hands of the hardware trade, their salesmen must become acquainted with the general technical conditions surrounding the installation and operation of such equipment. On the other hand, if it is left to electrical contractor-dealers these latter must inform themselves of the principles underlying the business of retailing. It is probably a toss-up which way would offer the least resistance, but it is reasonably certain that the hardware men will not give up a promising line of business without a struggle, and that if the electrical contractor wants to keep the distribution of electrical devices and equipment in his own hands he must hustle—right now.

Successful Anniversary Session of Toronto Section American Inst. Elec. Eng.

The 15th anniversary of the formation of the Toronto branch of the American Institute of Electrical Engineers, which was at the same time the 344th meeting of the parent Institute, was held in Toronto on November 22-23, at the Engineers' Club, and will long be remembered for the splendid efforts of the officers and members of the Toronto section. There was a record attendance at the reading of the papers and at the various functions, and the keenest interest was evidenced by the members and friends of the Institute in the proceedings throughout.

The officers of the parent society arrived in Toronto on Friday at noon and were entertained by the Toronto executive to luncheon at the Engineer's Club. Following a few remarks by the President, the technical session began immediately with Mr. Arthur H. Hull, electrical engineer, Hydro-electric Power Commission of Ontario, reading a paper on "Power Development in the Province of Ontario." This paper is reproduced in liberal extract on other pages of this issue. An interesting discussion followed Mr. Hull's paper, in the course of which Mr. F. A. Gaby, chief engineer of the Commission, explained the plans of the Commission to build up a network of distribution covering Eastern Ontario from power developed on the St. Lawrence River, which would be tied in with the Niagara System at some point east of Toronto, so that practically the whole of the province could, in an emergency, be fed from either the Niagara Falls or the St. Lawrence system.

The second technical paper was read by Mr. W. G. Gordon, transportation engineer Canadian General Electric Company, on "The Electrical Equipment of the Canadian

Number Tunnel in Montreal." Mr. Gordon's paper is extracted elsewhere in this issue.

In the evening, at 6.30, the delegates and members met at the Engineers' Club, where the guest of honor was Sir Robert Falconer, president of the University of Toronto. Sir Robert gave a splendid address, describing certain phases of his recent visit to the front line trenches in France, where he had been the guest of General Currie on the evening preceding and during the days which followed the battle of Amiens. Sir Robert emphasized the value of this war to Canadians in teaching them their powers of organization. This was in no way better illustrated than in the operations of the four divisions under General Currie, where everything moved like clock-work and every man, as if automatically, performed his duty. Canada has, of course, lost much in the war, but she will have made a corresponding gain if the lessons of organization that have been learned are put into effect in the business life of the nation during the reconstruction period and afterwards. Sir Robert paid a glowing tribute to the work of the Canadian engineers in France.

Mr. Arthur H. Hull, chairman of the Toronto section, in thanking Sir Robert for his fine address, spoke of the very large number of graduates and under-graduates of the School of Science—some 600—that had responded to the duty call in defence of the Empire.

At 8 o'clock the meeting adjourned to the Chemistry and Mining Building of the University of Toronto, where Mr. S. Svenningson, designing engineer of the Shawinigan Water and Power Company, Montreal, described the 110,000 volt transmission line over the St. Lawrence River. This paper is reproduced in full elsewhere in this issue.

On Saturday morning the delegates assembled at 9.30 at the Engineers' Club and were motored away, as their choice prompted, for an inspection of the Leaside Munitions Plant, the British Forgings and Steel Plant, or the Hydro-electric Laboratories on Strachan Avenue, returning for the final luncheon given by the reception committee at the rooms of the Toronto Board of Trade.

The proceedings throughout were a splendid tribute to the energy and ability of the officers of the Toronto section of the A. I. E. E. Everybody worked hard, from the chairman to the last member of the entertainment and reception committee, but special recognition is due Mr. A. H. Hull and the secretary, Mr. E. V. Pannell.

Canada's Need

Canada is fortunate in possessing a large number of valuable waterpowers. It is unfortunate in possessing apparently a large number of people who are anxious to prevent the development of these waterpowers.

Although in the muck-raking literature of the last ten years, the development of waterpowers has come in for an undue share of attention, few people realize that after all some 90 per cent. of the total amount of power utilized on the continent of North America is developed from coal by means of steam plants, and that only about 10 per cent. is developed from waterpower.

This overwhelming use of steam power, as against water power, is due to the economic reason that it was cheaper to put in the steam plants and operate them, than to develop waterpowers under the conditions surrounding the development of these waterpowers.

Waterpowers have important uses. The principal economic use of waterpowers to-day is to serve these industrial purposes where the load is practically continous. Such loads include the grinding of wood pulp, the operation of large industrial plants which operate continuously, and principally the operation of electric furnaces where, combined with the continuous use of power, is to be had a further advantage in the high temperature of the electric arc.

Canada is similar to some other northern countries, such as Norway, in having waterpowers. The coal which Canada possesses is limited and located in the extreme East and West of the country, so that the expense of getting the coal is now, and probably will be higher than in countries like England and the United States. It is therefore essential that the waterpowers be utilized to the maximum extent possible, so as to decrease the amount of coal which is purchased from abroad. By using one of our own resources instead of buying the material outside the country, a distinct economic gain accrues, always provided that the expenditure for the waterpower itself, the method of development etc., are undertaken and carried through in such a fashion that there will really be a saving by its operation.

The total amount of energy used for lighting purposes, and for the small user, that is the home user or the minor factory, does not exceed 25 per cent. of the total energy developed for electric power purposes. The other 75 per cent. is used for industrial purposes by a relatively small number of consumers, namely—the capitalists who have been held in such scorn.

For the last several years, the tide has been turning against the Government owned and controlled and operated electric power systems, and to-day few people in their ordinary senses would recommend the distribution of electric power by public bodies.

Arguments may be advanced to show that lighting is really a public utility, and should be a Government enterprise, and arguments may be advanced properly that Government control should be exercised to see that suitable precautions are taken both in the formation of the companies and in the control of the rates; but, dealing with the great resources which this country has in its waterpowers, it is more than obvious that in order to obtain rapid development of these waterpowers, with immediate benefit to the country, private concerns must furnish the money. Conditions made by the Government must be such as will attract private individuals and stimulate enterprise.

The Dominion of Canada, and particularly the Province of Quebec, has a great opportunity in the next few years of establishing a vast series of waterpower developments. Such developments will lead to the investment of large amounts of money, the employment of many men during the construction period, and the establishment of huge industries to use the electric power when developed.

With the creation of these industries will come the ability to export from this country the products made with electric power; and we will thus be turning into money natural resources which are now being wasted, and bringing that money back into this country to add to our wealth.—From an article by Mr. Julian Smith on the subject "Canada's Need," in the Montreal Star.

The Electric Club of Toronto

Two specially fine meetings of the Electric Club of Toronto were held on November 15 and November 22. On the earlier date the Hon. Geo. S. Henry, L.L.B., Minister of Agriculture for the Province of Ontario, addressed the members on "Agriculture—Yesterday and To-day," pointing out the progress that had been made in the rural districts of this province in spite of the tremendous handicaps of labor shortage and the competitive fertility of the western provinces as grain-growing areas. Mr. Henry also referred briefly to the improvement in the province's live-stock, pointing out that an Ontario-bred animal was recently sold for a price which constituted a record for this continent. Mr. Henry also

took occasion to rectify certain misapprehensions that have been expressed by the city man from time to time that the rural communities had not done their share either in supplying man-power or money towards the prosecution of the war and gave figures to show that the percentage subscribed both in population and in wealth was at least equal to anything the larger centres could boast.

On November 22nd the Club was addressed by Mr. Arthur V. White, consulting engineer to the Commission of Conservation on "Canada's Heritage in the St. Lawrence River." Mr. White's paper is reproduced in full elsewhere in this issue. On the latter occasion the Club was honored with the presence of Mr. James White, assistant to the chairman of the Commission of Conservation.

Montreal Electric Luncheon

After an interval of several weeks, due to the influenza epidemic, the Montreal Electrical Luncheon resumed its meetings on November 20. The speaker was Mr. E. S. MacNab, of the train lighting department of the C. P. R., who described the organization of a standard Canadian railway. He pointed out the high degree of organization necessary for the smooth working of a railroad, and incidentally referred to the good results of co-ordination in the allied forces and in the Victory Loan Campaign. The appointment of Marshal Foch and the pooling of supplies and funds had gone a long way to achieve victory. Canadian railroads had an approximate mileage of 32,700 miles, and 5,300 locomotives. Germany, said Mr. MacNab, had to hand over to the Allies within about 200 locomotives of the entire total in Canada.

The speaker then gave details of the system on which railroads are run—from the president down to the trackmen, pointing out how various departments are controlled by the vice-presidents, how the lines are split up into divisions, and how the work is minutely sub-divided. The electrical work is, from the administrative point, handled in different ways on various North American roads. Mr. MacNab also contrasted the Old Country methods of controlling railroads with those on this side, stating that the different conditions called for varying systems. A collection for the Red Cross fund totalled $41.50.

Sympathetic references were made to the deaths of Mr. F. N. Ormsbee, of the Standard Underground Cable Company of Canada, his wife and child; Mr. H. E. Randall, of the Shawinigan Water & Power Company, and Mrs. Burnett, wife of Mr. F. C. Burnett, of the Canada Cement Company.

50-Ton Electric Locomotives for Hydro

Twelve 50-ton electric locomotives are being built by the National Steel Car Company, Ltd., Hamilton, Ont., for the Hydro-electric Power Commission of Ontario. They will be used for hauling trains on the construction railway which is being built in connection with the power development at Chippewa Creek near Niagara Falls. Operation will be at 600 volts, direct current.

The locomotives are designed for double-end operation, with general dimensions as follows:

Length over all	35 ft.
Truck centers	19 ft.
Length of main cab	10 ft.
Length of auxiliary cab	9 ft. 6 in.
Width over side sills	9 ft.
Height from rail to top of floor	4 ft. 6½ in.
Height from rail to top of cab roof	12 ft.

Details of Construction

The underframe is made up of I-beams and channels. The center, side and intermediate sills are 12-in. I-beams running continuous from end sill to end sill to which they are secured by connection angles. The end sills are 12-in. channels extending straight for 15 inches on each side of the center line and dropping back 13 inches to the corner of the underframe. Cross-ties, of which there are five, consist of 8-in. I-beams connected to the longitudinal sills by angle connections. The bolster is composed of 14-in. x 1-in. plates riveted to the top and bottom of the longitudinal sills. The flooring, except in the cab, consists of cast-iron blocks 2¾ in. thick with checkered surface.

The draft gear is of the Miner twin spring type with M.C.B., class "G" spring and keyed-yoke connection to the M.C.B. coupler.

The cab is of all-steel construction, except the roof, which is made of poplar tongued and grooved and covered with 8-oz. cotton duck. The side and end posts are 3-in. channels, while the corner posts are 3½ in. x 3½ in. x ¾ in. angle. The outside sheathing is No. 16 gauge sheet steel, and is lined inside with wood lining. Each side of the cab is provided with two drop-sash windows and one swing door. Each end is provided with two stationary windows, one drop sash window and one swing door. The doors are in diagonal corners as are also the drop-sash windows. All control levers and handles are duplicated in diagonal corners for reversible operation.

The hood at each end of the cab is of all-steel construction and is composed of angles, channels and No. 16 gauge sheet steel. Inside the hood are the air compressor, large sand box, air-operated sanding device, and electrical equipment and a removable steel door is provided for easy access. The hood is narrow enough to allow a walkway around the outside of the platform. A pipe railing is provided at the outside edge with a hand railing around the top of the hood.

Trucks are of the arch bar design, with inside-hung brakes, 5½-in. x 10 in. journals and 36-in. diameter wheels. Each truck bolster is composed of two 10-in., 40-lb. rolled I-beams supported by helical springs. Each truck is provided with two inside hung 125-h.p. motors suspended from brackets secured to channel transoms.

Special Air Equipment to Operate Dump Cars

The locomotives are being equipped with Westinghouse air brakes, with 14-in. x 12-in. type "S" cylinders, the main reservoirs, parasite reservoir and radiating pipes being located on the top of the floor at the side of the hood. Two D-4-P, 50-ft. Westinghouse motor-driven compressors will furnish sufficient capacity to supply air to the dumping mechanism on twelve 20-yard dump cars, and the parasite governors are provided and so arranged that when operated in trains all governors will cut in at the lowest setting pressure in the series, and will prevent the dumping apparatus from depleting the pressure available for braking below a safe predetermined minimum. The hand-brake equipment is operated from inside the cab by a vertical hand wheel connected by bevel gears to a shaft running through the cab floor.

The locomotives will be equipped with multiple-unit control, six having General Electric control and six Westinghouse control. Each locomotive will develop at starting a tractive effort of approximately 30,000 lbs. on dry rails.

The Canadian Bond Hanger and Coupling Company have moved their plant from Alexandria, Ont., to a very modern and up-to-date building at the corner of Villiers and Munition Streets, Toronto. The head office of the company will also be at this address. Sufficient ground adjoining the plant has been purchased to render capacity for expansion almost unlimited. The company state that in the new plant they are already in a position to double their former output.

Block Bus System of Distribution

Owing to the unfortunate circumstances resulting from the influenza epidemic, a recent meeting of the Toronto section of the A. I. E. E. was cancelled. At this meeting it had been announced that Mr. G. E. Stoltz would read a paper on "Steel Mill Electrification," and in this connection we have an interesting letter from Mr. A. H. Winter-Joyner, referring to the "block bus" system now being more generally used in the transmission and distribution of large blocks of power for short distances. Mr. Joyner sends us an interesting discussion on this system which followed the reading of a paper at a recent meeting of the Association of Iron and Steel Electrical Engineers, which is so timely and full of interest that we reproduce it in full. The members of the Association had just completed an inspection of the Carnegie Steel Company's mills at McDonald, Ohio.

Discussion on "Block Bus" System of Distribution

D. M. Petty: As to distribution system, if feeders run through the plant to a sub-station, and from step-down transformers to some particular mill, one feeder for each mill, a large number of feeders will be the result. This system of distribution is called the "Radial" feeder system. There are other systems and the one which we have been looking at to-day is known as the "block bus" system. I believe we would be glad if Mr. Gaudy would give us a discussion covering what he considers the advantages of the block bus system.

R. J. Gaudy: Undoubtedly, it came to the mind of a number of you that it was rather an unjustifiable step to take, considering methods previously common. In this installation which we saw to-day, the engineers for the Carnegie Steel Company were, after careful study, assured that this project justified the move towards a newer type of simplified distribution. It should be gratifying to them to note that groups of engineers elsewhere have recently met distribution problems in handling large blocks of load over reasonable distances, and have adopted identical solutions. It is obvious that the block power bus scheme is partially applicable only where the blocks of load or load centres are sufficiently large, and so located that a double transformation is uneconomical. It should be considered comparable only to other methods of distribution having similar selection of voltage. The block bus scheme is, of course, not applicable where the items of load are very small, and so widely separated that they do not lend to handling from reasonable load centres. There are under construction at this time, some fine examples of similar distribution.

In station construction, it is commonest practice to use a bus for distribution from large blocks of generating capacity to adjacent switching positions. The McDonald installation is identical in scheme, the only change being the location of the bus switch at the load block, and the extension of the length of the bus between the supply and the load with the elimination of the lines otherwise necessary between the bus switch and the load centre switch.

The difference between the block bus distribution system and that of any other type, gives rise to some surprise until you overlook the novelty of the thing and consider its advantages.

1. The conductors are bare copper in air; which condition is the most advantageous possible considering the disposition of heat produced by losses.

2. The conductors are rigid and are ruggedly supported so that no difficulty can arise from mechanical stress developed magnetically.

3. The insulating medium is free from possibility of becoming moisture soaked and breaking down.

4. The conductor is insulated by a material which will not fail or deteriorate under temperature change. This feature is one which, for steel mill load, presents great advantage. Changes in the load requirements may occur on very short notice. Production in one portion of the mill may be doubled or trebled during a period which will not allow of procuring and installing additional distribution line material. The block bus system may be installed so that all characteristics are best selected for the anticipated loads, but when local or general increases come on there is absolutely no danger of failure due to temperature damage to insulation. This is of great advantage to the steel mill electrical engineer because his distribution will immediately take on a load addition which would be an undue overload on any other distribution having equal conductor in place.

5. The switch gear necessary for any loading is much reduced, for instead of a multiplicity of lines protected by individual switches and against each other, you instal a bus line so well that it will not get into trouble and are limited only to the capacity of switch gear available, which is at this time no mean limit.

6. If the location of the load blocks suggest either a block bus line or loop, loads may be added at any point, requiring at the most only the addition of bars to the stack to restore accurate characteristics desired.

The fact that the operating characteristics of bar copper in air are not so widely known as the characteristics of other transmission materials is mainly because they have not been so universally used in the past decade. The values of all characteristics such as power loss, voltage drop, regulation, temperature rise, a.c. resistance and reactance were predetermined and have been verified in the bus system at McDonald. All the data bearing on these characteristics are available and the bus design may be now handled just as intelligently as any other conductor arrangement on which you have accumulated information.

Wm. M. Hornlein: Are conductors tapered?

R. J. Gaudy: Yes, they are tapered as the load is taken off.

D. M. Petty: Condensation in a place of that kind will occur where there is marked change in temperature in a comparatively short time. If the change in temperature occurred slowly, the moisture in the air practically takes care of itself.

Wm. M. Hornlein: Any possibility of moisture causing corrosion, etc., of the supports? In other words, what will be the up-keep of the system?

R. J. Gaudy: The equipment installed has been protected against possibility of corrosion. The insulation selected by the engineers here will allow for insulating at that voltage during heaviest rainfall, which condition it would, of course, be impossible to obtain in that tunnel.

V. L. Crawford: Is this the first installation of this kind of distributing system?

R. J. Gaudy: It is, I believe, in the steel mills. Some of the central stations and construction engineers have gone into it very extensively. I do not know of any bus installation now operating that is any longer than this present bus. For one item of load there are several installations of that kind, that is, where one block motor load utilizes the entire line. I believe the installation you saw to-day, however, still has the blue ribbon. I believe the blocks are sufficiently large to allow that.

Max Nain: Would maintenance be cheaper on block type?

R. J. Gaudy: Yes, and the possibility of failure due to overload almost absolutely eliminated.

A correspondent would like to hear from any man who contemplates striking a match in South Kensington, with a view to sharing same.—Punch.

Power Generation in Ontario on Systems of Hydro-Electric Power Commission

By Mr. Arthur H. Hull*

The Province of Ontario is the largest and most populous of the Provinces in the Dominion of Canada, having an area of 407,262 square miles and a population (census 1911) of 2,523,274. Ontario's population is about 35 per cent. of the total of Canada's population, and its area is 10.9 per cent. of the total area of the Dominion. Ten per cent. of its area is water.

Ontario has developed into the greatest manufacturing Province in Canada and as there are no coal deposits in the Province, its abundant water power resources are being more and more utilized to furnish the power required for its varied and increasing industrial development. Other fuels, such as natural gas and petroleum are found in the southern part of the Province, gas along the north shore of Lake Erie and petroleum near Sarnia. The natural gas supply, however, is insufficient for present purposes and the quantity of petroleum produced does not begin to meet the needs of the Province. The demand for electric power has increased during the past ten years to such an extent, that, with the war industries in operation, it became necessary to impose restrictions on private and municipal consumers in order to provide the power required by the war industries. The great saving in coal effected by the use of electric power in Ontario's industries is one of the most important aspects of the electric power situation, and further great savings can be, and will be before long, brought about by the electrification of the steam railroads.

Mr. H. G. Acres, (hydraulic engineer, Hydro-electric Power Commission), in a monograph on Water Powers of the Province of Ontario, written in 1915, gives the following summation of water power capable of development, and of water power already developed in the Province:

Division	Potentiality	Developed.
Ottawa River & Tributaries....	688,000 h.p.	71,000 h.p.
Great Lakes Tributaries..	446,000 h.p.	137,000 h.p.
Hudson Bay Slope..	250,000 h.p.	22,000 h.p.
James Bay Slope	1,500,000 h.p.	70,000 h.p.
International Boundary Rivers..	2,045,000 h.p.	462,000 h.p.
	4,929,000 h.p.	702,000 h.p.

Of the above total for power developed, about 69,000 horse power is used in pulp and paper manufacture, about 59,000 horse power is used as hydraulic power directly applied, and the balance 574,000 horse power is converted into electric energy for light and power.

This paper will deal only with the generation of electric power by the Hydro Electric Power Commission of Ontario which is now the largest producer and distributer of electric energy in the Province

The Hydro Electric Power Commission of Ontario, which will be referred to hereafter as the Commission, was formed by the Ontario Government in 1906, and first furnished power over its 110,000-volt lines from Niagara Falls in October 1910, the power being purchased from the Ontario Power Company of Niagara Falls, Ontario. It was not until August 1st, 1917, that the Commission obtained direct control of the generation of power at Niagara Falls, through the Ontario Power Company, but in other parts of the Province, the Commission had started to develop its own power by constructing a hydro-electric plant at Eugenia Falls on the Beaver River near Flesherton, which was put into operation in November 1915, and one at Wasdell's Falls on the Severn River which was started in service in October 1914. In 1914 the Commission acquired by purchase the Simcoe Railway and Power Company, whose generating station at Big Chute on the Severn River had previously supplied power under contract to the Commission's Severn System, supplying the district around the southern part of Georgian Bay. In March, 1916, the Government of Ontario purchased the entire holdings of the Electric Power Company which, through subsidiary companies, was generating power on the South River near Nipissing, on the Otonabee River at Peterboro, and on Trent River at Healy Falls, Frankford, Campbellford, and Trenton. The operation of the equipments thus acquired was placed in charge of the Commission in June, 1916.

The various areas in the Province served by the Commission are designated by systems as follows:

System	Main transmission voltage	Frequency	Phase	Power obtained from
Port Arthur System ...	22,000	60	3	Kaministiquia Power Co.
Nipissing System	22,000	60	3	Comm's Nipissing Station
Muskoka System	22,000	60	3	Comm's So. Falls Station
Wasdell's Falls System.	22,000	60	3	Comm's Wasdell's Falls Stn.
Severn System.	22,000	60	3	Comm's Big Chute Station
Eugenia System	22,000	60	3	Comm's Eugenia Station
Central Ontario System.	44,000	60	3	Comm's { Healy Falls Stn. Auburn Station Campbellford Stn. Frankford Station Trenton Station
St. Lawrence System ..	26,400	60	3	M. F. Beach Company
Rideau System	25,700	60	3	Rideau Power Co.
Niagara System	110,000	25	3	{ Comm's Ontario Power Co's Station Canadian Niagara Co. Electrical Development Co. Queenston Development (future)

Port Arthur System

In the Port Arthur system, power is purchased at 22,000 volts, three phase, 60 cycles from the Kaministiquia Power Co., and is delivered to the City of Port Arthur at 22,000 and at 2200 volts, part being transformed in the Commission's Transforming Station in Port Arthur, containing two banks of transformers, each consisting of three 750 kv.a. units connected star-delta neutral ungrounded.

In order to take care of the future requirements, the Commission now propose to construct a Hydro-electric station on the Nipigon River at Cameron's Pool, about 80 miles from Port Arthur, which will have an ultimate capacity of about 50,000 horse power. The engineering work is now under way for this development. It is proposed to transmit the power at 110,000 volts, three phase, 60 cycles, to Port Arthur. Three other power sites on this same river, when developed, will, together with the Cameron's Pool site, give a total of 150,000 horse power. The needs of the Port Arthur district should, therefore, be amply provided for, but if additional power should be required for this district, another site is capable of development at Silver Falls on the Kaministiquia River about 25 miles from Fort William where with a 350-ft. head a total of 25,000 horse power can be developed. At the present time the electric energy supplied

*Electrical Engineer, Hydro-Electric Power Commission of Ontario, and Chairman Toronto Section A.I.E.E., before Toronto meeting A.I.E.E., November 22, 1918.

at Port Arthur is used for operation of the street railway, for public and domestic lighting, and for large grain elevators, ship yards, coal docks and miscellaneous industrial purposes.

Nipissing System

The Nipissing System, formerly controlled by the Nipissing Power Company, comprises a generating station on the South River near Nipissing Village, sub-stations in Callander, Powassan and North Bay. The generating station contains two 450-kw. three-phase 3200-volt 60-cycle 450-rev. per min., horizontal generators with 12.5-kw. 125-volt direct-connected exciters, each unit direct coupled to a water wheel of 925 b.h.p. at 86 ft. head. Water for this plant is taken from the South River through an open canal 900 ft. long, then through a wood stave pipe 6 ft. diameter 2300 ft. long to a differential surge tank 72.5 feet high, close to the power house, a steel penstock connecting thence to the turbines. The storage pond has an area of about 100 acres and the drainage area of the river is about 350 square miles. Provision was made for extension, and by additional storage works, it is possible to increase the capacity to 2500 horse power.

Muskoka System

The power house on the south branch of the Muskoka River at Muskoka Village was formerly owned by the Municipality of Gravenhurst and was taken over by the Commission in the latter part of 1915, and has been remodelled and enlarged, and now supplies power over a single circuit 22,000-volt, three-phase, 60-cycle line about 26 miles long to Huntsville, and at 6,600 volts three phase, 60 cycles, to the municipality of Gravenhurst over the municipality's line.

The equipment in this station now comprises one 450 kv.a., three phase, 6,600-volt, 720-rev. per min., 60-cycle generator, direct connected to a 500 b.h.p. turbine, and one 750-kv.a. similar 720-rev. per min. generator, direct connected to a 1,000 b.h.p. turbine. The hydraulic head at this plant is 102 ft. The water is conducted through one steel and one wood stave pipe, each 946 ft. long to the turbines.

Wasdell's Falls System

This system comprises a hydraulic generating station on the Severn River at Wasdell's Falls near Severn Bridge, and sub-stations at Beaverton and Cannington. Power is transmitted to Beaverton and Cannington over a single-circuit steel conductor line at 22,000 volts, three phase 60 cycles, and over a single circuit aluminum tie line at the same voltage to the commission's Severn system, connecting at Longford with the town of Orillia 22,000-volt lines from Longford via Orillia to the Big Chute generating station.

The generating station is interesting on account of the low hydraulic head. The normal head is 12 ft., but variations from 9 to 15 ft. occur. The equipment consists of two 400 kv.a., 90 rev. per min., vertical type 60 cycles, three-phase, 2,300 volt generators connected through flexible couplings to turbines rated at 600 horse power at 100 per cent. gate opening with 12-ft. head.

Severn System

This system comprises a hydraulic generating station on Severn River at Big Chute with substations as shown in the diagram. The generating station as originally built in 1909 by the Simcoe Railway and Power Company contained three 900 kv.a., three-phase, 2,200 volt, 60 cycle, 300 rev. per min., horizontal-shaft generators direct connected to turbines each rated at 1,300 horse power under 56-ft. head. An extension to the building has been made by the Commission during the past year, and there is now being installed one 1600 kv.a., three phase, 60 cycle, 2,200 volt, 300 rev. per min. horizontal generator direct connected to a 2,300 h.p. turbine. The switching equipment is being rearranged to provide a double high-tension bus for greater flexibility in operation. Space is left for a a third bank of transformers, and for two future 22,000 volt line equipments. A double low-tension bus is installed. All power is transmitted at 22,000 volts, three phase, over four lines. An interesting feature of the transmission lines of this system is the long spans across Matchedash Bay at Waubaushene, one being 1,135 ft. long and one 858 ft. long. The west shore tower is 175 ft. high, the middle and east shore towers are 88 ft. high. No. 00 B&S 19 strand copper conductors are used on these spans.

The water is taken from the river through a canal 500 ft. long to the head works and then through two steel penstocks 170 ft. long to the turbines.

Eugenia System

This system obtains power from a hydraulic generating station constructed by the Commission at Eugenia on the Beaver River and was placed in service in November 1915. Extensions are now almost completed to provide double the output. This development is one of the most interesting in Ontario, and has the distinction of having with one exception, the highest hydraulic head of any plant in Canada, being 552 ft. gross. It is also one of the highest heads in the world using reaction wheels.

The first installation consisted of two 2250 h.p. turbines each direct connected to 1410 kv.a., three-phase, 4,000 volt., 60 cycle, 900 rev. per min., horizontal shaft generators having neutral grounded without resistance. The extensions cover enlargement of the building to accommodate two additional generating units, one of which is now being installed, and for double high-tension and low-tension busses, and for six 25,000 volt. feeders. The new unit consists of a 2,810 kv.a., three phase, 60 cycle, 720 rev. per min. horizontal maximum-rated generator direct connected to a 4,000 h.p. turbine.

The success of this development depended upon the storage of the water of the Beaver River and for this purpose two large storage dams were constructed. From the head works, a wood stave pipe 46 in. in diameter conducts the water 3,400 ft. to the Johnson differential surge tank which is 105 ft. high. From this tank a 52 in. diameter steel pipe is carried 1,550 ft. to the power house, which is a brick building 69 ft. wide, 112 ft. long and 34 ft. high above the generator room floor. Actual tests made at this station after the first installation was completed in 1915 gave an overall full load efficiency of 80 per cent. which shows how carefully the design was worked out.

Additional power for the Eugenia system will be obtained, when required, by the construction of further water storage systems and of a second pipe line at the Eugenia Falls development and the installation of a fourth unit, also by the construction of a station on the Saugeen River near Lake Huron which, operating in parallel with the Eugenia Station, will make available a total output for the system of 15,000 h.p.

Three Systems Tied Together.

The Eugenia system comprises 245 miles of 22,000 volt. circuit (176 miles of lines) supplying substations at the points shown on accompanying diagram, and 50 miles of 4,000 volt circuits. This system is connected to the Severn system by means of a single-circuit, three-phase tie line from the Eugenia generating station to Collingwood, a distance of 24 miles. By means of this tie line and the tie line from Wasdell's Falls to Big Chute mentioned above, the Eugenia, Severn, and Wasdell's systems are paralleled. The generating station of the Town of Orillia on the Severn River at Swift Rapids near Big Chute is also connected into the Severn system.

Central Ontario System

Five main generating stations, one on the Otonabee River and four on the Trent River, all operating in parallel,

supply this system. These are now fully loaded and plans are being prepared for new stations near Campbellford to provide additional power. The five exciting stations were built by the subsidiary companies of the Electric Power Company. The following table gives the data relative to the existing developments, all generators being three-phase, 60 cycles, with 25 per cent overload guarantees:

Location	Gross head feet	Rated Turbine capacity h.p.	Type	Generator voltage
Trenton.	20	1400	Vertical	6600
Frankford.	18	1200	Vertical	6600
Campbellford . . .	23	1100	Vertical	2400
Healy Falls . . .	76	5600	Horizontal	6600
Auburn	18	950	Horizontal	2-6600 1-2400

In addition to the above stations, a 1000 kv.a., three phase, 60 cycle, 120 rev. per min. horizontal generator owned by the town of Campbellford in its generating station, a short distance north of the Campbellford station, delivers its output to the 2,400 volt bus in this station. Also at Fenelon Falls, a small generating station is operated, containing two 400 kw., 600 volt, three phase, 60 cycle, 200 rev. per min. generators connected to two 700 h. p. turbines. These feed into the 44,000 volt net work of the Central Ontario system at Lindsay the voltage being stepped up in the generating station through two banks of transformers to 11,000 volts for transmission to Lindsay. All these stations are on the route of the Trent Valley Canal the dams having been constructed by the Government of the Dominion of Canada.

Other power sites along the Trent Valley Canal will when developed, provide about 60,000 electrical h.p. with a maximum capacity of 75,000 electrical h.p. The present power output of the system is used for lighting, street railway and manufacturing purposes, a considerable quantity being required at Campbellford for a pulp and paper mill, and near Bellevil'e for cement mills. All transmission lines are constructed on wood poles. The total mileage of 44,000-volt circuits is 372, with 15 miles of 11,000-volt circuit, 16.4 miles of 6600-volt circuits and 52 miles of 4000-volt circuits.

St. Lawrence System

This system at the present time has no generating station owned by the Commission. Power is secured by contract from the hydraulic station of the M. F. Beach Company at Iroquois, but the amount obtainable proved inadequate and was supplemented by power obtained from the steam generating station of the town of Brockville. As additional power is needed arrangements are now being made to obtain an adequate supply from another source, near Cornwall. To take this power the Commission is now constructing a transforming station near Cornwall which will contain one bank of three 1250 kv.a., single-phase, 63,500/26,-400-volt, 60-cycle transformers connected star-delta and switching equipment for two incoming 110,000-volt circuits and for two outgoing 26,400-volt circuits. This system now supplies power to Brockville, Prescott, Morrisburg, Winchester and Chesterville.

Rideau System

A new net work is being developed called the Rideau system and covering a district in the neighborhood of the Rideau River. Plans are now being prepared for a hydraulic generating station at High Falls on the Mississippi River near Clarendon, a point about 50 miles northerly from Kingston, Ontario. The installation at this point will consist of four 350 k.w., 2200 volt. three-phase, 60-cycle, 300-rev. per. min. horizontal generators connected to two turbines, one generator being at each end of turbine; and one 875 kv.a. 80 per cent. power factor, three-phase, 60-cycle, 2200-volt, per min. generator direct connected to its turbine with necessary switching and transformer equipment to transmit the full 2,100-kw. output, at 26,400 volts to the Rideau system. A portion of this system is now in operation, power being obtained at 26,400 volts, three-phase, 60-cycles, under contract from the Rideau Power Co. at Merrickville, and transmitted to Smiths Falls where at the substation the municipality's own generating stations are paralleled with this system on the low-tension bus. This system may ultimately be connected with the St. Lawrence System.

Niagara System

The Niagara system comprises all lines and substations that receive power from Niagara Falls, and covers the entire district from Niagara River to the Detroit River and east to Toronto. Power is received at a transformer station at Niagara Falls from the Ontario Power Co. (now controlled and operated by the Commission) and from the Canadian Niagara Power Company, at 12,000 volts, three-phase, 25 cycles and is transformed to 110,000 volts and to 45,700 volts for transmission. There is now installed in the Niagara transformer station 132,000 kv.a. of 110,000-volt transformers in eight banks and 42,000 kv.a. of 45,700-volt transformers in four banks, not including spare units. Four banks of 110,000 volt units are composed of twelve 7500 kv.a., single-phase, shell-type 12,000/63,500-volt transformers, all other transformers being of 3500 kv.a. rating. This station, in point of transformers capacity, is the largest in the world, having a total capacity of 174,000 kv.a., with 7,000 kv.a. in spare units additional.

Four outging 110,000-volt circuits feed to Dundas transformer and switching station and from there power is distributed to thirteen 110,000-volt transformer stations. Four 45,700-volt lines feed to Welland to the substations of the Electric Steel & Metals Company, the Union Carbide Co. and the city of Welland. From this latter point a single-circuit, 45,700 volt line runs to Dunnville.

The transmission net work on this system contains 760 miles of 110,000-volt circuits; 65 miles of 45,700-volt circuits; 529 miles of 26,400-volt circuits; 489 miles of 13,200-volt circuits; 27 miles of 6,600-volt circuits; 180 miles of 4000-volt circuits; and 20 miles of 2,200-volt circuits. The 110,000-volt and 45,700-volt circuits are carried on steel towers (with exception of one 45,700-volt line from Welland to Dunnville), while the other circuits mentioned above are standard wood pole line construction.

The Commission in 1917 purchased the Erindale Power Company which had a hydraulic generating station on the Credit River at Erindale, 14 miles west of Toronto, containing two 600-kw. three-phase, 60-cycle, 13,200-volt. 200 rev. per min. generators, each direct-connected to a 1,000 h.p. turbine designed for a 60-ft. head. The present operating head is about 50 ft. The output of this station is transmitted to the Cooksville transformer station at 13,200 volts, 60 cycles, and is fed into the 13,200-volt, 25-cycle bus in that station through a 1000 kv.a. 60/25-cycle frequency changer set, augmenting the power supply on the Niagara system, and serving also to raise the power factor at the Cooksville station.

The generating plant of the Ontario Power Company, taken over by the Commission in 1917, contains 14 generator units, generating 12,000-volt, three-phase, 25 cycle power with a total rating of 149,012 kv.a. The Commission is now making extensions to the generating station. The building is being extended north about 90 ft. and a third pipe line of temporary nature consisting of wood stave pipe is being constructed. Two additional generating units are being installed each rated at 15,000 kv.a. maximum rating at 75 per cent. power factor.

These new generators are the same speed as the previous units namely 187.5 rev. per min. and the frames are the

same size as the 8775 kv.a. units most recently installed. They have, however, a higher temperature guarantee and are so designed that they may be operated as synchronous condensers at zero power factor if it ever becomes necessary to remove them from this station. These generators were made in Canada, under war conditions, and all parts, except the laminated steel and the insulation, were produced in this country. This speaks well for Canadian industry in these trying times.

The Ontario Power Company obtain some power from the Electrical Development Company's generating station at Niagara, this being brought into the distributing station on two 12,000-volt feeders. When the present extensions to the distributing station are completed, there will be six main bus sections connected together through reactors. Three of these bus sections will supply the power delivered to the 12,000 volt bus in the Commission's transformer station to which the feeders from the Canadian Niagara Power Company are also connected through a bus reactor. The concentration of generator capacity on this 12,000-volt bus is consequently very great and has necessitated material changes in the switching equipment and bus construction. The studies covering the installation of reactors on this 12,000-volt system have been most interesting. There is no 12,000-volt bus in the generating station, and each generator feeds through an automatic oil circuit breaker in the generating station to its individual cables in the cable tunnels up the hill, thence to its group of circuit breakers in the distributing station, where switching arrangements are such that each generator and each feeder may be connected to either of two bus sections. In the Commission's Niagara transformer station there is a single sectionalized 12,000-volt transfer bus system so arranged that feeders are connected through an auxiliary bus to the main bus or direct to a transformer bank.

It is of interest to note that the cables for the two new 15,000 kv.a. generators were purchased after laboratory tests were made on manufacturers' samples to determine the dielectric losses and tendency of compound to flow, and guarantees on dielectric losses were obtained from the contractor.

Another interesting point in connection with the feeders entering the Commission's transformer station is that eight of these are three-conductor, armored cables laid directly in the earth without ducts. These armored cables all have sector-shaped conductors, with 8/32-in. x 8/32-in. paper insulation, a lead sheath and a double steel tape armor with jute bedding and jute covering. They are placed three feet below the surface and two and three feet apart centre to centre. Where these buried cables cross ducts containing other cables, arrangements are provided to moisten the surrounding earth either by sprays above the surface or by porous tile in the ground.

The Queenston Development

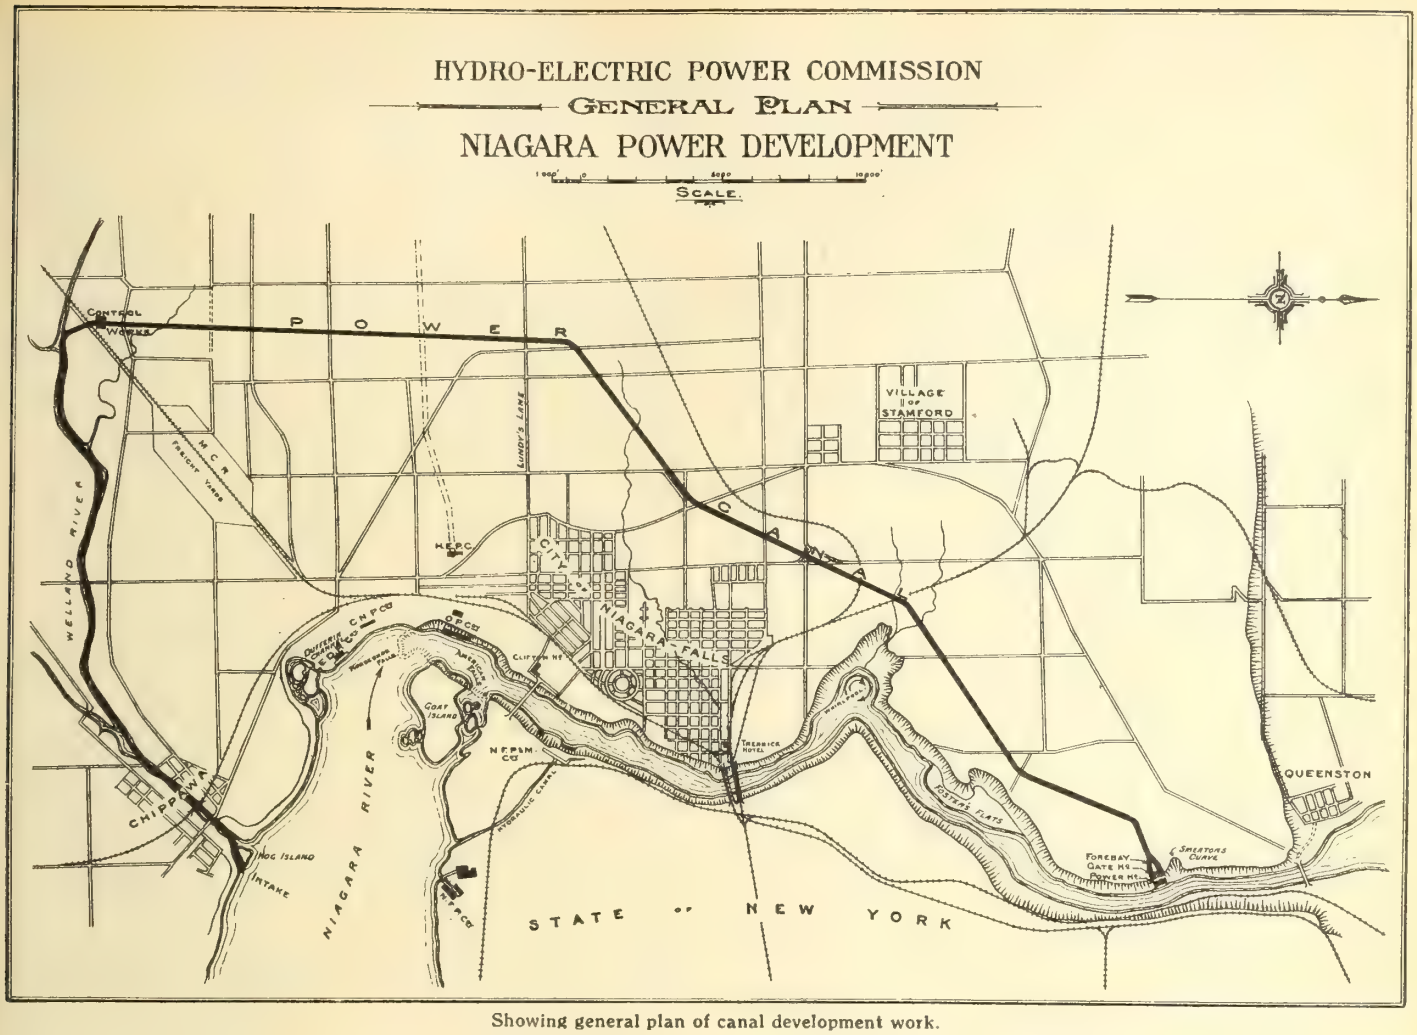
When the Commission in March, 1908, contracted with the Ontario Power Company for 100,000 horse power, it was thought by many that such amount of power would meet the requirement for many years. This supply was however exhausted in 1915 that is, in 5 years from date of first delivery of power, and the additional power secured by arrangements with the Canadian Niagara Power Company has proved insufficient to meet the demands. It became necessary therefore to look to a new development to secure a further supply and the final decision was to proceed with a development called the Queenston Development which is authorized by an Act passed by Ontario Government in April, 1917, called The Ontario Niagara Development Act.

Between Lakes Erie and Ontario there is a difference in elevation of 330 feet. The greatest net head now utilized on the Canadian side at Niagara Falls is about 160 ft. Canada is entitled to divert 36,000 cu. ft. per second from the Niagara River, and of this amount, by an Ontario Government Order in Council in 1915 the Commission were allotted 6610 cu. ft. per second. The Ontario Power Company were allotted 11,180 cu. ft. per second, so that, within the control of the Commission, there is now available 17,799 cu. ft. per second.

To obtain the greatest amount of power from the water available, after careful surveys and studies, it was decided to locate the generating station just above Queenston, and to take water from the Niagara River, through the Welland River (reversing the flow in same) and canals encircling the City of Niagara Falls to Queenston. The first canal is now under construction and the accompanying map of the Niagara District, shows its location.

The total length of waterway from the Niagara River to the generating station site is about 12½ miles, 4¼ miles of this distance being in the Welland River, and the balance in an excavated canal The net effective head will be about 305 ft. and the first canal is normally designed for 10,000 cu. ft. per second at minimum low water.

The generating station will be located about one mile up stream from Queenston, in the Gorge, just at the end of the last rapids in the river. At this point the banks are steep and short penstocks only will be required. Provision is being made for extensions, and right-of-way for two additional canals has been purchased.



To show the effect of utilizing the greatest possible head of water, it may be pointed out that about 30 h.p. will be developed for each cubic foot per second in this development. whereas about 14 h.p. is all that is obtained in existing plants at Niagara Falls.

The development now under construction is designed as regards canal, forebay, gate house substructure and power house substructure, for a capacity of 300,000 h.p. It is proposed to construct the gatehouse and power house superstructure for an initial installation of 200,000 h.p. in four units. The designs are made so that extensions of power house and gate house can be made to almost any extent. Future plans contemplate the use of 100,000 h.p. units.

The turbine speed has been fixed at 187.5 rev. per min., and specification for the generators are now being issued calling for 45,000 kv.a., 85 per cent. power factor, 12,000 volt, three-phase, maximum-rated generators of vertical type equipped with thrust bearings to take the weight of the rotating part of the generator plus the downward thrust of the turbines. Direct-connected exciter mounted above the thrust bearings are proposed. The generators will be liberally equipped with embedded temperature detecters so that close and accurate observations may be kept of operating temperatures. The specified maximum temperature of any part of the generator at rated load is 100 deg. cent. with cooling air at 40 deg. cent. The ventilation problem for such units is of great importance, each unit requiring approximately 125,000 cu. ft. of air per minute. It is proposed to install double 12,000 volt sectionalized buses, banks of transformers consisting of three 15,000 kv.a., single-phase units, and to lay out the switching equipment so that one generator, one bank of transformers, and one outgoing high-tension line will be a unit. Bus tie reactors will be provided, and the short-circuit current will be limited to a value that can safely be handled on the circuits and circuit breakers.

It is proposed to install two small service generators to supply power required for the station services such as pumping, cranes, lighting, machine shop, ventilating, etc.

To carry on the construction work on this development it was decided to make as extensive use of electric power as possible. Two large electrically operated revolving shovels each fitted with an eight-cu. yd. bucket for earth excavation and of capacity to handle a five-ton bucket in rock were provided. The larger or these two shovels has a boom 90 ft. long and a dipper stick 80 ft. long, while the smaller shovel has a

Showing general plan of canal development work.

boom 80 ft. long and a dipper stick 58 ft. long. Each shovel has motors of a nominal total rating of 715 h.p. on a half-hour rating. Three shovels weigh over 300 tons each and have a capacity of 5,000 cu. yd. of earth per day. Five other electrically operated shovels are also provided, having bucket capacities ranging from ⅞ to 4½ cu. yd.

The railway equipment of the construction work includes 150 dump cars of 20 cu. yd. capacity each, six 40-ton steam locomotives and twelve 50-ton electric locomotives.

The electric power required for shovels, trains, air compressors, etc., is obtained from the Ontario Power Company's station and is transmitted over two overhead feeders to the Whirlpool Substation located near the Whirlpool. A similar substation will shortly be erected near Montrose on the southerly section of the canal. The Whirlpool substation is of semi-permanent construction and contains switching equipment for the two 12,000-volt incoming lines, and for three 1,500 kv.a., 12,000/4,000-volt transformers, four 500 kw. 600-volt, d-c. synchronous converters with their 12,000-volt transformers. An adjoining room contains eight air compressors of 1,000 cu. ft. per minute capacity each against 125 lb. pressure, belt driven from 550-volt motors, supplied through two banks of 200 kv.a., 2300/550-volt transformers. Air is distributed up and down the canal for a distance of three miles from this substation to operate rock drills, channellers and forges, etc.

Power is distributed up and down the canal by 4,000-volt, 25-cycle, three-phase, four-wire, grounded-neutral circuits to which the shovels are connected through flexible armored cable. A double track railway has been built for the full length of the canal with a branch to the main dumping point at St. Davids. These railway lines are electrified, the trolley wires being offset to one side of the track so as not to interfere with the shovels.

The substation at Montrose will be identical with that at Whirlpool and it will similarly serve to supply power for the work on the upper end of the canal.

The extensive use of electric power on the construction of works of the magnitude of this development is working out well and is resulting in a great saving of coal.

Electrification of Montreal Tunnel

By Mr. W. G. Gordon*

Following the discussion on Mr. Hull's paper, Mr. W. G. Gordon, Transportation Engineer of the Canadian General Electric Company, gave a very complete description of the electrification of the Montreal Tunnel zone. He explained that the tunnel is designed to provide at the same time an entrance for the Canadian Northern Railway System into the heart of the city and to render available a large area for residential purposes. As Mount Royal stood in the way of these two projects it was necessary to excavate a tunnel 3.1 miles long. This tunnel has a uniform grade of .6 per cent. towards the city. The paper described that different cross-sections were used, depending on the geological formation. The twin-section type of tunnel was used throughout.

Work was carried on from each end of the tunnel and also from a shaft sunk about a mile from the end known as the West Portal. When the headings on one side met, the lines checked within 1/16th inch on alignment and ¼

*Transportation Engineer, Canadian General Electric Co., before Toronto meeting A.I.E.E., November 22-23, 1918.

inch on grade, and on the other side the error was only ¾ inch in alignment and ¼ inch in grade.

Mr. Gordon explained the method employed in driving the tunnel, which was to drive a bottom centre heading about 8 feet by 12 feet wide from which the full-sized excavation was developed in a number of places. Four drills were used in each heading, supported on a horizontal bar and operated by compressed air at 100 pounds pressure, the aggregate capacity being about 11,000 cubic feet of air per minute.

The Montreal Light, Heat and Power Company supply power for the operation of the tunnel at 63 cycles, 3 phase, 11,000 volts. Direct current is provided by two motor-generator sets, each 750 kw., 1,200 volts, with an overload capacity of 200 per cent. for 5 minutes. The overload capacity is obtained by the use of a pole face winding; this winding of tubes and rods through holes near the pole faces is so connected as to directly oppose the armature reaction. In the paper, Mr. Gordon described all of the electrical eqiupment in detail.

There are at present six locomotives in operation, the motor equipment of each consisting of four GE-229-A, commutating pole motors wound for 1200 volts and insulated for 2,400 volts., two of the motors being permanently connected in series for operating on the 2,400 volt trolley circuit. This voltage is obtained by operating the motor-generators in series. Each motor is rated at 320 h.p. Mr. Gordon further explained the complete electrical equipment of the locomotives.

The speaker described at length the multiple unit motor cars at present in course of manufacture for handling local traffic. The principal dimensions of these cars are as follows:

Length over buffers	67 ft. 5¾ ins.
Length over body corner posts	57 ft. 6¼ ins.
Truck centres	42 ft. 9 ins.
Width over side sill angles	9 ft. 10½ ins.
Width over eaves	10 ft. 2¾ ins.
Height top of rail over roof	13 ft. 0 ins.
Height top of rail to underside of side sill	3 ft. 7½ ins.
Centre to centre of body side bearings	4 ft. 10 ins.
Centre to centre deck sills	5 ft. 6 ins.

The motor equipment of these cars consists of four GE-239-A, 125 h.p., 1,200 volt, commutating pole motors, insulated for 2,400 volts, two of the motors being permanently connected in series. The complete electrical equipment of the cars was also given in detail.

Mr. Gordon explained that special local conditions and temperatures introduced features which required a design of the catenary system somewhat out of the ordinary. The pantograph is of the sliding type and the conductor wire is of special bronze composition, size No. 0000 with a breaking strength of 65,000 pounds per square inch. Its section is the standard of the A. E. R. A. for No. 0000 grooved trolley wire. This wire was used in preference to hard-drawn copper, because of its longer life when subjected to the wear caused by the sliding pantograph, and also because it could be pulled up tighter than copper on account of its greater strength.

The article was illustrated throughout by lantern slides.

Canadian Independent Telephone Convention

The 13th annual convention of the Canadian Independent Telephone Association was held commencing November 20 with headquarters at the Carls-Rite Hotel, Toronto. A splendid attendance was recorded and the papers read and topics discussed were unusually bright. A resolution was adopted urging that, in cases where highways are being widened in connection with the Ontario Government's highway policy, the Government in all cases assume the expense incurred in moving poles and other equipment. Some of the papers read at the convention were as follows: "A Troubleman's Experience on a Rural Telephone System," by Dr. W. Doan, Harrietsville; "Financing a Telephone System," the local company, by James McEwing, Drayton, and the municipal system, by Francis Dagger, telephone adviser of the Ontario Railway and Municipal Board; "Increased Telephone Costs and Rates," A. D. Bruce, Stouffville, and "Keeping Books for a Local Telephone Company," by George Tait, Bridgeburg.

Officers Elected

The election of officers for the ensuing year resulted as follows: Honorary president, F. S. Scott, Brussels; president, Myron A. Gee, Selkirk; vice-president, A. McLean, Paisley; secretary, A. Hoover, Green River; treasurer, F. D. Mackay, Toronto. Executive—Col. T. R. Mayberry, Ingersoll; S. Suddaby, Burnt River; G. W. Jones, Port Hope; James McEwing, Drayton; Anson Groh, Preston; J. R. Forbes, Waterford; R. A. Harrison, Dunnville; C. J. Johns, Algonquin; F. E. Webster, Creemore; George Tait, Bridgeburg; W. R. Wadsworth, Byron; Dr. W. Doan, Harrietsville; E. E. Wilson, Caledon; P. R. Craven, New Liskeard, and Dr. A. N. Hotson, Innerkip. Auditors, George Tait and R. A. Harrison.

Bell Telephone Co. Asking Increased Rates

The hearing before the Board of Railway Commissioners in the matter of the application of the Bell Telephone Company of Canada for an increase in tolls and in the matter of the application of the municipal corporation of the cities of Montreal, Toronto, Hamilton and the Union of Canadian Municipalities for an order directing the delivery of particulars by the telephone company, is proceeding at Ottawa. The Bell company have submitted statements for the years 1913 to 1917, the following being the figures for the years 1913 and 1917:

	1913	1917
Gross operating revenue	$8,397,463.49	$11,179,162.07
Operating expense	3,214,564.73	4,545,328.05
Annual maintenance	1,549,978.25	1,595,366.19
Depreciation	1,660,000.00	2,470,000.00
Taxes	190,648.22	422,427.22
Other deductions:		
Total expenses	6,635,191.20	9,033,121.46
Net operating revenue	1,762,272.29	2,146,040.61

The total expenses from January 1 to September 30, 1918, were shown to be $7,483,739, and the net operating revenues for the same period, $1,552,653.

The total capital liabilities for the above period were shown to be $29,149,000, and the total current liabilities $1,258,266.14. The value of the company's lands and plants to September 30, 1918, book value, was shown at $43,200,362.77.

The estimated new revenue that would be produced by the proposed 20 per cent. increase, according to the statement, is $1,200,000. Summarized the statement shows:

Exchange revenue	$1,200,000
Long distance revenue	20,000
Service connection charges	115,000
Moving and change of name charges	125,000
Total new revenue	1,460,000

Additional statements were furnished by the company, bearing on maintenance charges, etc.

A recent court decision in Toronto was in favor of a woman who was said to have sustained internal injuries as the result of a fall when a strap, to which she was holding in one of the cars of the Toronto Street Railway, broke. The jury, under Chief Justice Meredith, were of the opinion that the company was negligent in not maintaining the strap in a safe condition and that $1,000, in the way of damages, would go far toward alleviating the plaintiff's suffering.

110,000 Volt Transmission Line Over the St. Lawrence River

By Mr. S. Svenningson*

The Shawinigan Water & Power Company has for a number of years been transmitting power from the generating plants at Shawinigan Falls located north of the St. Lawrence River about 20 miles from Three Rivers, one branch running to Sherbrooke and supplying various towns and industries between, the other branch feeding the asbestos mines and other industries in the Thetford district. The current is transmitted at 50,000 volts from Shawinigan Falls to the St. Lawrence, where the voltage is stepped down to 25,000 for transmission across the river over the submarine cable, then stepped up to 50,000 volts and transmitted at this voltage to Thetford and Sherbrooke.

At the time the submarine cables were installed, the alternative of putting in an overhead crossing was considered but the amount of power to be transmitted at that time was so small that it was decided that the expense of an overhead crossing was not warranted. However, the demand for power on the south shore steadily increased, until by the beginning of 1916, five submarine cables were in operation, two three-phase and three single-phase, and the capacity of the transformer house, 10,000 kw., had been reached.

Submarine cables have always been a weak point in this part of the system and a source of more or less trouble and expense. The current in the river carries them down stream and is sometimes strong enough to pull them apart. In the winter the ice has often put them out of commission, and it has been found necessary at times to erect temporary pole lines across the ice to maintain the service to the south shore. When, therefore, in the Fall of 1916, the demand came for more power for the south shore, partly for war work, and it became a question of putting in an additional submarine or an overhead crossing, the Company decided in favor of the latter.

The construction of an additional submarine crossing would have involved an expenditure of about $150,000 for the purchase and installation of the cables, additional transformers, about 4000 kw. capacity, together with their switches, lightning arresters, etc. and the necessary extension of the transformer houses. Besides this, the weak point in the line would not have been improved.

The overhead crossing was estimated to cost $200,000 the difference between the two being offset, in the opinion of the company, by the elimination of the weak link, in obtaining greater security from interruptions to the service, and a gain of from 2 per cent. to 3 per cent. in regulation by cutting out the transformers together with the elimination of a considerable amount of operating and maintenance expense. The transformers and other equipment were needed and could be used to advantage in other parts of the system.

Preliminary Investigation

The two shores of the St. Lawrence River upstream, as well as downstream of the cable houses were carefully surveyed in order to find the most advantageous point of crossing. As a result of this preliminary survey it was finally decided to investigate in detail two alternatives:

a. A three-span crossing at Point-du-Lac, each span approximately 2,200 ft long.

b. A single-span crossing between the cable houses 4,800 feet long.

From a construction point of view the site at Point-du-Lac, about six miles up the river from the cable crossing appeared at first to be very favorable for an overload crossing. The St. Lawrence at this point is about 7,000 ft. wide, but as the water is very shallow, except for a distance of 2,000 ft. in the centre, a crossing could have been built using three spans of approximately 2,200 ft. each. The towers on either side of the main channel would have been about 205 ft. high, while the other two towers would have been about 110 ft. high. Although this alternative probably would have been somewhat cheaper, i.e. the cost of the crossing itself it would have necessitated the building of about 15 miles of double-circuit high tension pole lines in order to connect up with the main transmission lines. This additional cost would have brought the total cost approximately up to that of the single-span scheme. A fairly strong point against the three-span crossing was the inaccessibility of the towers during certain periods in the spring and fall when the river is full of floating ice. The single-span scheme was finally decided on as being the most advantageous, although it was fully realized that there were many difficult problems to solve in connection with the design and construction.

General Description

The crossing as completed consists of a central span 4801 ft. long and two anchor spans, the north shore span 571 ft. long and the south shore span 951 ft. long.

There are two towers 350 ft. high and 60 ft square at the base, the upstream and downstream faces tapering to a width of 14 ft. at the top. A cross-arm at the top, 14 ft. wide by 100 ft. long, carries three double-groove sheaves 8 ft. in diameter and 50 ft. apart, over which the anchor cables pass. The tower foundation is made up of four circular reinforced concrete piers 11 ft. in diameter placed on the corners of a 60-ft. square. These piers are connected by heavily reinforced concrete beams 4 ft. wide by 8 ft. deep.

Three lines of cable 50 ft. apart span the river between the two towers. The cables are 1⅜ in. in diameter made of galvanized plough steel. They are composed of six strands of 19 wires each and a stranded core of 30 wires. To each end of the centre span cables is yoked two anchor span cables. These are carried over the tower on the 8-ft diameter sheaves and then down to a point about 20 ft. from the anchors. At this point equalizing beams are cut in the lines and the load is transmitted from this point to the anchor piers by means of short straps of 1¾ in. diameter cable. The cables are gripped at the end by means of heavy steel bridge sockets in accordance with the usual practice for suspension bridge cables and other structures of this type.

It was originally intended to use the main cables as conductors and to insulate them from the tower by specially designed insulators. Unfortunately these insulators were not completed in time for erection, and for the present the main cables are used as messengers from which No. 1/0 stranded copper conductors are suspended. These suspended lines are supported every 250 ft. by suspension insulators of eight units to a string.

The anchor piers are large mass concrete "dead men,"

* Designing Engineer, Shawinigan Water & Power Co., before Toronto meeting A. I. E. E.

being designed to take the full overturnig moment when submerged

Foundations

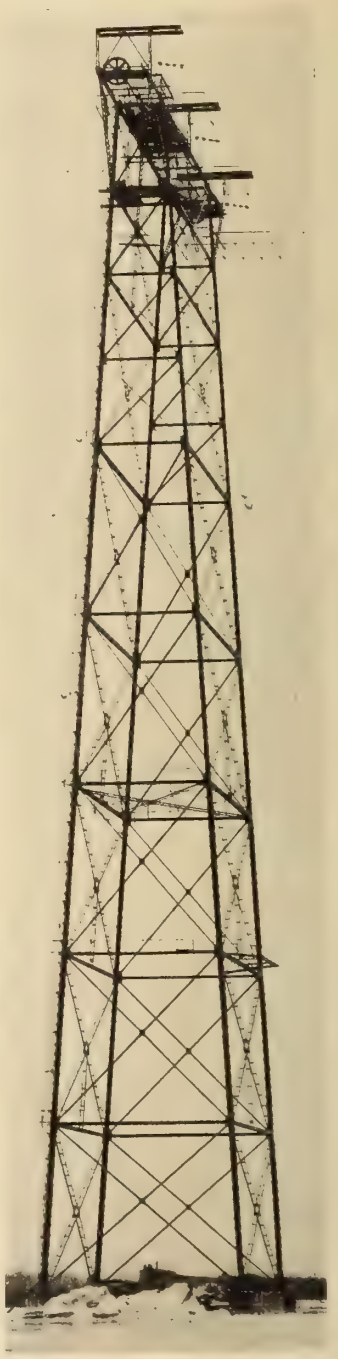
During February, 1917, a number of borings were taken at the site of the towers to determine the nature of the river bottom. These borings penetrated to a depth of 100 ft. and we found that the foundation on which we would have to build out towers consisted for the full depth of these borings of very fine white sand with occasional strata in which a little clay was mixed with the sand. The difficulty of obtaining a secure pile foundation in this kind of soil and the uncertainty as well as the cost of placing a mat foundation in the dry, led us to adopt the form of pier foundation which we used.

The piers were constructed in the form of hollow cylinders of reinforced concrete with an outside diameter of 11 ft. and an inside diameter of 7-ft. These cylinders or caissons were poured in 6-ft lifts, the first lift tapering on the inside towards the bottom to a diameter of 10 ft. and being shod with a 6 by 6-in. angle cutting edge. This lift was poured on the working platform and lowered into the water by means of four two-in. screws. The second lift was then excavated by means of an orange peel bucket rigged up on a derrick. As the caissons gradually settled successive lifts were poured until they had penetrated the bottom to a depth of about 40 ft.

Little trouble was experienced on the north side, but on the south side we encountered large numbers of boulders, some of which were so large that they could not be picked up by the bucket, so that we had to drill and shoot them. In order to do this the caissons had to be unwatered, a tedious process which delayed the work considerably. When a caisson had reached its penetration of 40 ft., a plug of rich concrete was poured in the conical section at the bottom and the inside was then filled with mass concrete. The four piers forming one foundation were finally connected by reinforced concrete beams.

This work was begun early in the year and we expected to have it finished by mid-summer, but high water, high winds, rain and labor troubles delayed us so much that it was not completed until about the middle of September.

Cables



The cables are 1⅜ in. in diameter, of galvanized plough steel, made up of six strands of 19 wires each, and a stranded steel core of 30 wires. Tests made at McGill University showed that the wires had an average yield point of 221,000 lb. per square inch, and an average breaking load of 258,000 lb. per square inch.

The completed cable was tested, the yield point being found to be 158,500 lb. and the ultimate strength 186,400 lb. or 193,000 lb. per square inch, and 227,000 lb. per square inch respectively.

The test of the completed cable, indicated a modulus of elasticity of 7,250,000 lb. or 8,800,000 lb. per square inch. We were in doubt as to the correctness of our test in this regard on account of the fact that the usually accepted value for the modulus for stranded steel cables is about 21,000,000 lb. per square inch. However, the behaviour of the cable during erection bore out the results of the test.

The bridge sockets used for connecting the cables were machined out of solid blocks of steel so as to allow a grip of nine in. on the cable. The cable was passed through a tapered hole in the centre of the bridge socket and broomed out on the end for a length of 15 to 18 in. The wires were then cleaned with gasoline and held in place by means of a templet made of ⅛ in. steel plate which fitted over the back of the bridge socket. The bridge socket was suspended bottom up and heated by gasoline torches for about half an hour, when spelter was poured into the conical hole through a one in. diameter hole in the centre of the templet. After being allowed to cool, the ends of the wires projecting from the templet were cut off and the templet was removed.

Before adopting this form of connection, tests were run under our direction at McGill University to determine the depth of socket required. We found that if the spelter was heated to just the right temperature, i.e., just hot enough to ignite a sliver of wood thrust into it, that the full breaking strength of the wire was, in the majority of cases, developed in a length of six inches.

North tower, St. Lawrence River Crossing, showing copper conductors leading from strain insulators on messenger cable through main tower.

Shortly after the bridge sockets were poured it was found necessary to shorten two of the cables and the speltered end was cut off. We had one of these cones of spelter cut in the

machine shop and found that the spelter adhered so firmly to the wires that the section could be machined without lifting the wires out.

Insulators

The insulators which we propose using eventually in the steel line were devised by our engineering department in conjunction with that of the Canadian Porcelain Company. They consist of a large ring-girder and two spiders.

The ring-girder is eight ft. in diameter and made up of two nine in. channels 12 in. apart, with ⅜ in. cover plates. The upper spider is connected to the ring-girder by means of three 2½ in. bolts 10 ft. long, one at the end of each spider arm. The centre spider is supported on the ring-girder by six porcelain insulators of eight skirts each, two insulators at the end of each spider arm. The clear distance between the spiders is about 36 in.

The porcelain insulators used are special compression insulators having a tested breaking strength of 60 tons each, this is about four times the estimated maximum load. Electrical tests showed a dry flashover of 302,000 volts and a wet flashover of 262,000 volts.

The completed insulator has a net weight of about 6 tons.

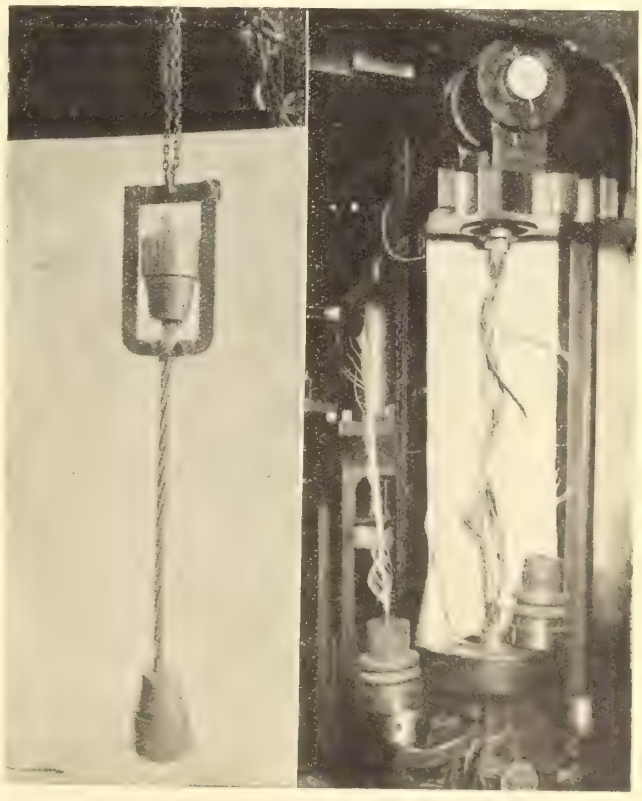
Erecting Cables

Owing to a constant succession of delays that occurred in the construction of the foundations and the erection of the towers we had to abandan our original plan of stringing the cables in the Fall of 1917 before the ice formed in the river, and so decided to do this part of the work after the ice had become thick enough to support the weight of the heavy reels of cable.

Throughout the heavy snows of January and February we managed by constant rolling and scraping to keep a road open between the two towers. Early in March the centre span cables were laid out along this road. The anchor cables were then laid out, measured, and cut and their bridge sockets attached.

The three lines were erected one at a time, the middle line first and then the downstream and the upstream lines in succession. The ends of the anchor cables were hoisted over the towers, the south shore cables were hoisted over the towers, the south shore cables made fast to the centre span cable, drawn over the tower until the bridge sockets touched the main sheave, tied to the top of the tower and attached to the anchor pier. The north shore cables were next attached to the centre cable, the suspension insulators and copper line fastened to this and the cable hoisted into place.

The hoisting was done by a steam hoist braced against the centre anchor pier. Two ⅝-in. steel hoisting lines reeved through the two pairs of three-sheave blocks were used to draw the end of the cable up to within 40 ft. of the anchor pier, the final 40 ft, being taken up by means of two ¾-in. steel cables reeved through two pairs of six-sheave blocks.



The copper conductor in each line is supported by seventeen suspension insulators spaced about 250 ft. apart, the end insulators being about 400 ft. from the towers. The copper lines drop from the end insulators to strain insulators on the tower at the 150-ft. level, pass through the tower to the back where they are connected to another set of strain insulators. On the north side, the lines pass direct from the main tower to a transmission line tower on the shore, a distance of about 600 ft. On the south side a light structural steel truss, 50 ft. long, hung from two sets of the anchor cables, provides an intermediate point of suspension, forming two spans of 500 ft. each. Access to the insulators attached to the truss is provided by a walkway running up from the anchor pier and suspended from the anchor cables.

After the cables were erected we noticed an almost constant vibration in them, varying in intensity and somewhat similar to that in a violin string, with definite nodes 12 to 15 ft. apart as nearly as could be judged. About a month after the line was put into service this vibration managed to shake loose the bolts connecting two of the suspension insulators to the cable and they dropped and hung suspended on the copper line. Two of the riggers volunteered to go out on the steel cable, fish up the insulators and attach them again. A trolley was rigged up and they had little difficulty in getting out to the point from which the insulators had fallen, about 1,000 ft. out from the tower. By means of a small tackle line they hauled the insulators back into place and started back towards the tower only to discover that the grade in the cable was so great that they could not pull themselves up. They solved the difficulty by looping the tackle line that they had with them over the steel cable and sliding down the 250 feet to a boat waiting below. A short time later an insulator on one of the other lines broke loose and it was similarly reconnected. This time, however, we profited by our former perience and provided a tail line by means of which the riggers were pulled back to the tower. Since then we have experienced no trouble from this source.

The cables, as originally strung, allowed the following clearances between the copper conductors and the average water level during the season of navigation:

Down stream	172.5 ft.
Centre	178.8 ft.
Upstream	180.6 ft.

The temperature at time of erection was about 20 deg. fahr. As there is a change in sag of approximately one ft. for each 10 deg. change in temperatuure the above would correspond roughly to clearances at 110 deg. fahr. of 163.5, 169.8, and 171.6 ft. respectively.

Cable test—Sample of cable with grips attached. Elastic limit 158,500 pounds; ultimate strength 186,400 pounds.

At the time these cables were erected we naturally expected the sag to increase as the cables stretched under the load until the strands were drawn tightly together. There was no data available with regard to the amount of stretch to expect so that it was impossible to allow for this in sag-

ing the cables. The hoist, therefore, was left in position so that we could pull up the cables when the sag became too great.

In May of this year we found that the sag in the cables had increased by from 24 to 27½ ft. and that in order to obtain the necessary clearance over the channel we would have to take up 34 ft. in the sag of the down-stream cable and 13 and 14 ft. in that of the centre and upstream cables respectively. The amount by which a cable is to be stretched in order to take up a given amount in the sag varies inversely as the modulus of elasticity of the cable.

Owing to the low modulus which we worked out for the cable from results of the tests made at McGill University we were in doubt as to the amount of take-up required. We found that in order to take up 24 ft. in the sag we would need to pull the downstream cable in between 7.2 and 10.4 ft. depending on the value of this modulus. This cable was taken in about 8 ft. with a consequent reduction in the sag of about 25 ft. This corresponds to the result that would be obtained if the modulus of the cable were 17,000,000 lb. In other words it would appear that from the time of the original sagging of the cable to the time the cable was resagged, the modulus of elasticity had increased from 7,250,000 lb. to 17,000,000 lb. This change in modulus is no doubt due to the gradual stretching of the cable causing the wires and strands to draw more closely together under the constantly applied tension of the span.

Ice Protection

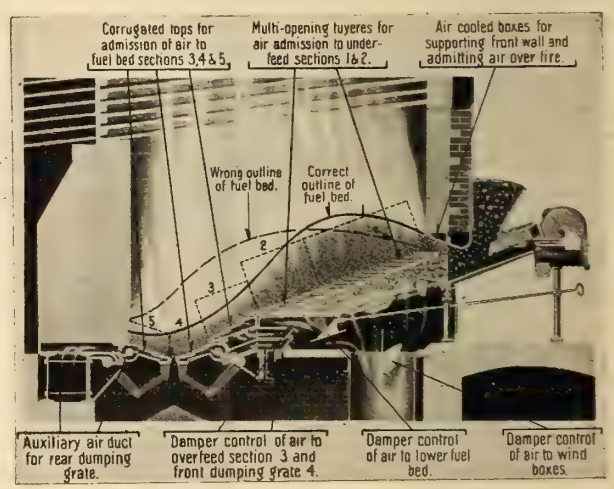
Ice conditions in the St. Lawrence River at this point are at times very troublesome, and we considered it advisable to construct some kind of guard piers outside the towers, to obviate the possibility of damage from this source. During the winter we deposited about 3,000 tons of field stone on the river bed on each side about 75 ft. from the up-stream and river faces of the towers, carrying the rock to an elevation about three ft. above the surface of the ice. The ice usually goes out about this level, but last year conditions were exceptional, and before the ice moved it had risen above the tops of our ice breakers, and passed clear over them, piling up around the tower foundations to a height of 25 or 30 ft. Fortunately no damage was done. We are at present completing the guard piers, by means of reinforced concrete cribs filled with rock, and carried to about the level of the maximum recorded high water.

Sag Calculations

In our calculations for sags, tension, length of cable, etc., under various conditions, we used the parabolic formulas in preference to the hyperbolic formulas for the catenary on account of the greater simplicity of the former. Comparison was made however, between the two sets of formulas and we found, as we had expected, that at working tensions the difference was negligible. The formulas for the parabola gave us about six in. more sag, and about one ft. less length of cable than the catenary formulas for the same conditions of tension and temperature.

The maximum load on the cable, we assumed to be ¾ in. of ice all round, and ten lb. of wind per square foot of projected area for both the steel and copper lines, at a temperature of zero deg. fahr. Under these conditions the calculated tension in the cable is about 106,000 lb. with a sag of 228 ft. The normal tension at summer temperatures is about 61,000 lb. with a sag of 185 ft.

Conclusion



In our design, we always kept in view the accessibility of various insulators and other working parts that are subject to break down. Automatic hoists have been provided in the towers, as well as ladders which run from top to bottom and provide access to the suspension insulators at various levels.

The crossing has been in uninterrupted service now for about nine months; it has not yet weathered a winter with its low temperatures, gales and sleet storms, so that we still have something to learn about its action under these conditions, but as the allowable stresses have been kept within reasonable limits, we hardly expect serious trouble from this source.

Prevent Smoke and Save Coal—Boiler Room Instruments Help Save Fuel

Just now every practical suggestion along the lines of fuel conservation is a matter not only of personal comfort but, what is vastly more important, of the national welfare. Naturally the best place to save coal is the place where it is being used, and the boiler room offers a fruitful field for the exercise of fuel economy. The following summary of the experience of the combustion engineers of the Westinghouse Electric & Manufacturing Company, as gained from their own experiments and their observations of practical operation in customers' boiler rooms, will therefore be of value.

The formation of smoke, which contains much unconsumed fuel, should be prevented by proper firing methods and the flue gases should contain from 10 to 12 per cent. of CO_2. Fires should be kept free from holes, and the fuel should be so distributed over the grate as to prevent the influx of excess air which accompanies thin fires and the incomplete combustion resulting from excessive thickness of fires. The proper fuel distribution for a given type of stoker is illustrated in the accompanying figure.

Gauges which indicate boiler operating conditions should constitute a part of the equipment of every boiler room. As a minimum, the instrument equipment should consist of draft gauges connected with the furnace above the fuel bed and on the boiler side of the flue damper, and a steam flow meter for each boiler. Gauges and dampers should be conveniently located, otherwise they will not be used.

The loss due to the presence of unburned fuel in the ash should be avoided, boiler settings should be kept air-tight and baffles in proper condition, and under no condition should live steam leaks be tolerated. Exhaust steam should be used in place of live steam for auxiliary purposes wherever practicable. All steam pipes should be insulated and the tubes kept free from soot and scale. The size of the coal has much to do with the capacity and efficiency of a boiler. In general, the air pressure penetrates a fuel bed formed of coarse fuel more readily than one formed of finer coal, producing greater disturbance of furnace conditions and lowered boiler efficiency.

Canada's Heritage in the St. Lawrence River

By Mr. Arthur V. White, M. E.*

About a year ago, when I had the pleasure of addressing the Electric Club, as you may recall, we traced the evolution of the circumstances associated with power development on the Niagara River, and noted how those circumstances led up to the ratification of what is known as The Boundary Waters' Treaty of 1910, between Great Britain and the United States, and to the formation, under the treaty, of the International Joint Commission, This treaty now largely governs the development and use of boundary waters, and is of great importance in connection with the subject before us to-day because it constitutes the chief legal agency—so to speak—for safeguarding the interests of the people, of both the United States and Canada, in the international St. Lawrence River.

In proceeding, it will, I believe, be profitable first to point out how it is that even a recent treaty like the Boundary Waters' Treaty sometimes fails to provide that effective protection to either one country or the other, which it had confidently been expected would be found actual and full. I shall illustrate by reference to some issues which have arisen under the Treaty and to some arguments advanced under discussion of these issues.

Let me here comment, that the best safeguard the citizens of Canada can have in matters affecting their natural resources, is an intelligent understanding of the real value of their assets and of the best uses to which they may be applied, coupled with a quick and discerning appreciation of what constitutes any menace to these interests, and of how to act promptly for its removal. Menace to public interest often manifests itself in obscure and subtle forms.

Let us proceed to consider a few illustrations which, owing to limitations of time, can here only be referred to suggestively:

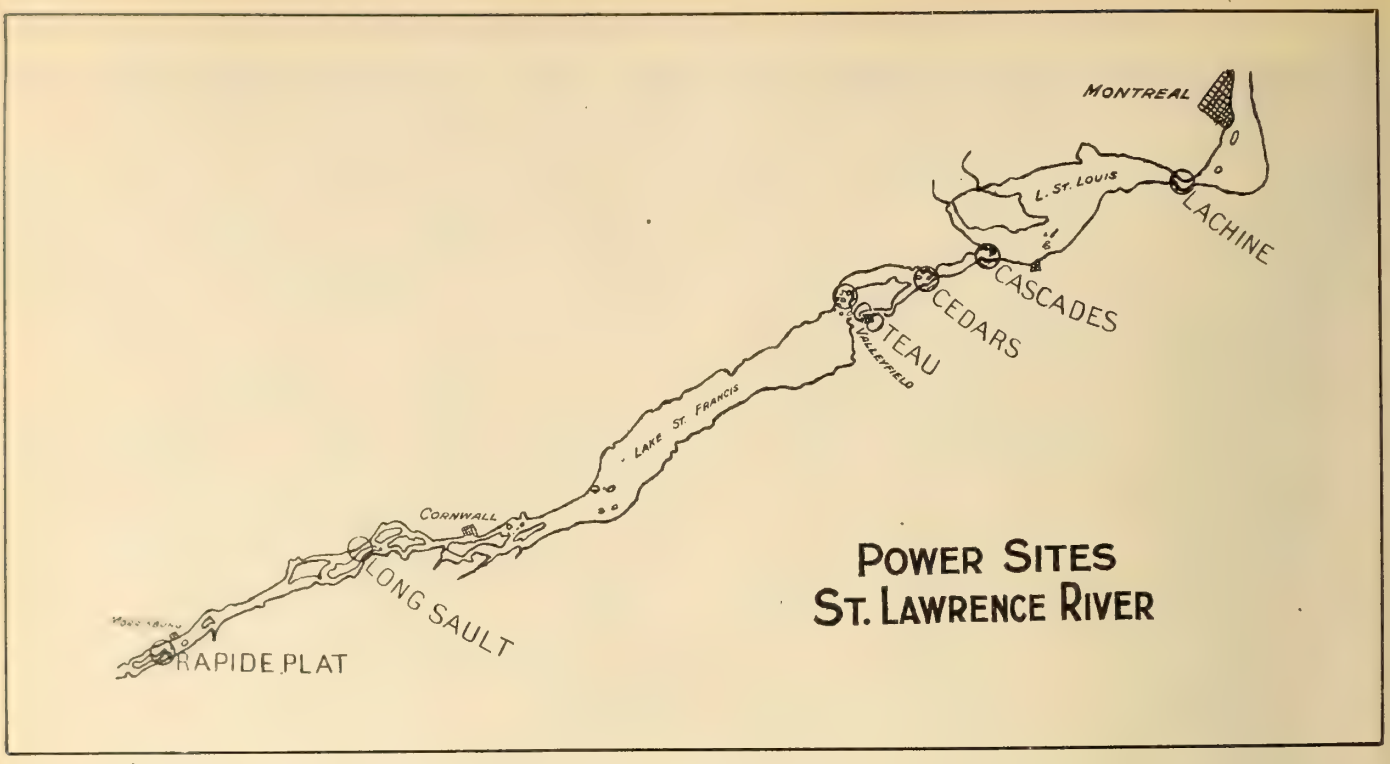
St. Croix River Application

The boundary line between the State of Maine and the Province of New Brunswick passes along the St. Croix River —a stream of considerable size. Four or five years ago United States financial interests controlling the St. Croix Paper Co. of the State of Maine, and operating in Canada through the Sprague's Falls Manufacturing Co., Limited—a company with a Canadian charter—undertook to increase the power installation which they already had upon the St. Croix River by erecting a new plant in the vicinity of what is known as the Grand Falls, situate about ten miles above Woodland, Me. The additional installation was to consist of 12,000 to 14,000 h.p., to develop which the company constructed a large canal lying and extending for nearly a mile entirely within the State of Maine. By means of a dam erected across the International Boundary at Grand Falls a lake was created so as to enable the water of the St. Croix River to be diverted by the canal into the United States for the development of power at the Grand Falls power house. This canal is so constructed that, at its lower stages, the total flow of the St. Croix River—an International Boundary stream—may be diverted into the United States. This company, after constructing their works, came before the International Joint Commission, pleaded ignorance of the law, drew special attention to their vested interests, and were finally granted a permit to utilize the works under terms greatly to their advantage.

Now, the Treaty provides that, after its acceptance, no diversion from boundary waters, whether "temporary or permanent," shall be made without obtaining the necessary authority. When the St. Croix case was under discussion, counsel suggested that the word "temporary" might not mean temporary with respect to time, but temporary with respect to place. That is to say, that the diversion of the St. Croix River was not out of accord with the treaty because the river was only diverted temporarily; that is, it was "temporarily" turned aside for a short distance and then resumed its normal course.

Navigation in Lake Michigan

Consider the next illustration: The Boundary Waters' Treaty defines boundary waters as "the waters from main shore to main shore of the lakes and rivers and connecting waterways, or the portions thereof, along which the International Boundary between the United States and the Dominion of Canada passes, including all bays, arms, and inlets thereof, etc." And the treaty also states: " It is further agreed that so long as this treaty shall remain in force, this same right of navigation shall extend to the waters of Lake Michigan and to all canals connecting boundary waters and now existing or which may hereafter be constructed on either side of the line."



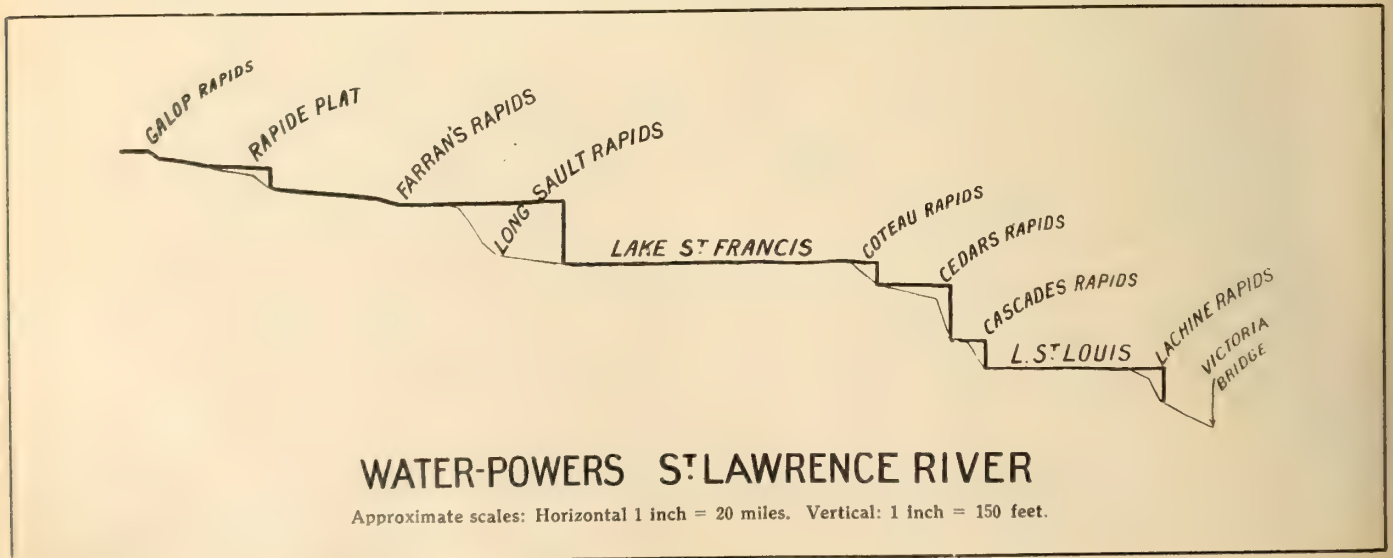
Now, the treaty, subject to certain restrictions, stipulates "that the navigation of all navigable boundary waters shall forever continue free and open for the purpose of commerce to the inhabitants and to the ships, vessels and boats of both countries equally," and one not acquainted with possible interpretations suggested for portions of the treaty, is naturally surprised to learn that it has been contended that Lake Michigan is not a boundary water—although a geographically corresponding body of water in Canada, the Georgian Bay, is such—and the treaty suggests, inferentially, that Lake Michigan is only conditionally open to navigation, while Georgian Bay—the Bay is not specifically mentioned—is open, but not conditionally open as in the case of Lake Michigan. Besides, assuming that the uninviting project of the Georgian Bay Ship Canal ever materialized, this canal, under the treaty, would be as equally free and open to the United States as to Canada. Of course, I am not arguing one way or another upon the points cited in my illustration, and I am passing over any reference to rights still existent under earlier treaties. I am simply suggestively pointing out certain facts which have been disclosed, and indicating certain contentions which have been offered, when subjects involving treaty terms have, variously, been considered.

Water Diversion from Niagara River

Take another illustration: The Boundary Waters' Treaty, in Article V., deals specifically with the diversion of waters for power purposes from the Niagara River, and provides that "so long as this treaty shall remain in force, no diversion of the waters of Niagara River above the Falls from the natural course and stream thereof shall be permitted except for the purposes and to the extent hereinafter provided."

When, during the last few years, certain interests desired to utilize a portion of the waters now flowing in the lower Niagara River, that is to say, below the Falls, the claim was urged that such waters could be used without coming before the International Joint Commission for permission, because it was contended that the treaty only dealt with diversion of water above the Falls and did not specify where the water should be returned. In other words, some interests hold that, under Article V., the International Joint Commission has no jurisdiction to deal with any diversion in the Niagara River other than with diversion made from "above the Falls." The water, it was argued, could be taken

*Consulting Engineer, Commission of Conservation, before The Electric Club of Toronto.



out above the Falls and turned, if users so desired, directly into Lake Ontario without coursing the lower Niagara River.

Application of St. Lawrence River Power Company

While illustrations might be multiplied, we shall here consider only one other instance. This arose during the past summer in connection with the application of the St. Lawrence River Power Company respecting the construction of works in the vicinity of, and the diversion of waters from, the Long Sault Rapids. The St. Lawrence River Power Company is a subsidiary company of the Aluminum Company of America, which, amongst other activities, operates a large aluminum-producing plant at Massena, N.Y. The St. Lawrence River Power Company desired to construct works in the St. Lawrence which would, so far as possible, remove ice difficulties which affected their winter output. To this end they excavated, largely in rock, a long channel, 25 feet deep by 150 feet wide, in the bed of the St. Lawrence River. Complementary to this excavation there was to be a large boom held by rock-filled cribs, some 30 feet square, sunk in the St. Lawrence River. Below the dredged channnel just referred to, there was also to be constructed in what is known as the South Sault Channel—that is, the passage nearest the United States' shore—a "submerged weir," which, actually, is a large submerged dam. The work of channel excavation was undertaken, and practically completed under permit from the United States War Department, without the matter in any way being brought to the official attention of the Canadian authorities.

The Boundary Waters' Treaty provides that there shall not be "any interference with or diversion from their natural channel of such waters on either side of the boundary" as will result in any injury on the other side of the boundary. If the enlarged channel remained, then the proposed submerged weir had to be constructed in order to compensate for alterations in level already resulting from the excavation. Incident to the construction of this weir the company deemed it desirable to obtain the approval of the International Joint Commission. Consequently, an application was made for hearing before the Commission. The company and the United States Government authorities stated that as a "war measure" it was necessary that the company be supplied with more power in order to produce more aluminum. The Com-

mission was urged to deal with the application of the company without delay and to waive rules of procedure which constitute the usual safeguards so far as the public is concerned. This course was urged although the company knew at least about a year before it made the application that the proposed dam would be necessary. Upon the war necessities Canada, of course, guaranteed every possible assistance and despatch.

In passing, I would like to remark that at times when certain issues have been under consideration before the International Joint Commission, and it appeared advantageous to interested parties to show how what might be done in boundary waters on one side of the boundary would affect the level of waters on the other side, it has sometimes been instanced that even a pile driven in a stream on one side would affect the level of water on the other. In the case of the large channel to which reference has just been made, which substantially affected levels in the river and adversely affected Canadian navigation, counsel for the applicant company argued that interests would really not be disadvantageously affected because when the large cribs and the dam was in place disturbed levels would then be restored.

Under the Webster-Ashburton Treaty it is specifically provided that the channels in the St. Lawrence River on both sides of Long Sault, Barnhart and Croil islands were to be kept "free and open to the ships, vessels and boats of both parties." So that, in any event, if the South Sault Channel were blocked by a dam, a navigable channel which was to be kept open by treaty right would be closed, and a public liberty and right which could not be justified under the spirit and intent of the treaty would be enjoyed by private interested parties.

Now, although the construction of the works referred to was, in the judgment of many, a violation of the spirit and terms of the treaty, the company, nevertheless, aided by their representations respecting the allies' war necessity, were able to obtain a permit to construct this dam and to have it remain in place for five years or for the term of the duration of the war, whichever term should be longer. You will notice it was not specified which term should be shorter. At the time of hearing before the International Joint Commission the solicitor-general of Canada, the Hon. Hugh Guthrie, on behalf of the Government of Canada made a special, solemn and very able protest against the granting of the permit except under conditions which he outlined, and which, while meeting temporary needs, would fully preserve the integrity of what he contended to be Canada's rights under the Webster-Ashburton Treaty.

From the foregoing illustrations it will be evident how necessary it is for our leading public men, especially those in Parliament, to have a good understanding of Canada's natural heritage in boundary waters and of means which must be taken properly to conserve this heritage for the benefit of her citizens.

Navigation of St. Lawrence River

We shall now consider, very briefly, some more concrete aspects of the subject which to-day has our chief attention: "Canada's heritage in the St. Lawrence River."

First, just a few words with respect to navigation. The St. Lawrence as the wonderful water highway from the Great Lakes to the sea has, as you know, been improved chiefly by the canal systems of the Government of Canada. The new Welland Canal is being constructed with locks of 30 feet draught. If it is to be used so that deep-draft, ocean-going vessels may go up to the head of navigation of the Great Lakes, then the St. Lawrence River in portions of its main channel will have to be canalized by means of a series of dams with suitable locks. If the river as a whole be canalized, obviously the water-power of the river would be most economically developed by having the dams necessary for the navigation improvement made adaptable also for the development of water-power. One fact is certain, and that is, that, in order to conserve the integrity of the St. Lawrence River so that it may suitably be canalized—when the time comes for such work—its integrity must not be compromised by permitting the erection of structures in the main stream for piecemeal development of power, although this has already been done to some extent. Naturally, there is a great temptation for water-power companies to do on the St. Lawrence as has been done elsewhere, namely, to make the cheapest possible preliminary developments—skim the cream off the powers, so to speak—for by so doing interests may readily acquire markets, and vested rights, and often control of the general situation.

I shall not further refer to Canada's heritage in the navigability of the St. Lawrence. In a word, it may be summed up that deep-craft navigation from the Great Lakes to the sea involves, absolutely, the treatment and canalization of the St. Lawrence River as a unit.

Water-Powers of St. Lawrence River

Coming next to the heritage of water-powers, I would remark first that the water-powers of the St. Lawrence River are, as yet, largely within the control of the people. The recent shortage of hydro-electric power which has been so keenly felt, both in Canada and the United States, has drawn increased attention to the enormously advantageous powers in and adjacent to International Boundary waters. Most of the water-powers which are more readily capable of economic development in Canada as well as in the United States either have already been developed or are privately controlled. Concentration of ownership is a noticeable feature of this control. Canada cannot afford to have her St. Lawrence River powers pass into the hands of powerful private interests.

Some Governing Factors

With respect to development of these water-powers, there are some very important points upon which I must just comment, such as ice conditions, the exportation of Canada's share of electrical energy and the character of the agencies utilizing the power.

Respecting Ice.—Power development on the St. Lawrence River cannot properly be considered apart from the subject of the ice menace. Too great caution cannot be exercised before attempting to harness natural forces of such magnitude as exist in the flow of the St. Lawrence River. Too radical a disturbance of the balance which Nature seeks to maintain may cause disaster, hence it is well to emphasize this phase of the problem, for it involves the weighing of basic physical factors of paramount importance.

Respecting character of consumption of power.—Where very large developments of power take place it is, as you know, usually necessary to have some industries, such as the electro-chemicals, take large blocks of power. These industries require cheap power. As the demand for power increases for municipal and small manufacturing purposes the experience has been that the demands for power for such uses become so urgent, and the inducements by way of price so attractive to the vendors of such power, that large industries which were attracted by the cheap power have been compelled to go farther afield. A block of power—over 65,000 h.p.—such as is exported from the Cedars plant in Quebec to the Aluminum Works at Massena, N.Y., would be sufficient, speaking on a broad basis, to supply light and power to some 35 manufacturing cities of 10,000 inhabitants each. It will be apparent from a comparison of the benefits resulting from power thus widely distributed and the localized benefits from the same power utilized in bulk, as in electro-chemical industries, that the former contributes in a much greater degree to the upbuilding of communities and

to the growth of the country at large. This feature should not be lost sight of.

Respecting the Exportation of Electrical Energy.—There is strong opposition, especially throughout Ontario, to any policy which permits the exportation of electric energy really required for use in Canada. The Federal Government has been memorialized upon this subject. It has been urged that no large power projects such, for example, as those on the international portion of the St. Lawrence River, should be developed without reserving Canada's share of the power for use here; and, further, that powers situated wholly in Canada should be reserved against the day of Canada's need. This statement is made having in mind the fact that it is not the policy of Canada to embargo her exports, but that commodities of national importance should not be exported without an adequate **quid pro quo.**

On the St. Lawrence River below Lake Ontario the first site where development involving the whole flow of the river could be made is in the vicinity of Morrisburg. With a dam near the foot of Ogden Island, a head of about 11 feet could be obtained, or, by taking in a portion of the Galop rapid, it has been thought possible to obtain a total effective head of about 15 feet. It is at this Morrisburg site—the Rapide Plat—that the New York and Ontario Power Company develops power in a small plant at Waddington, N.Y., under rights extending back for one hundred years. This company desires to reconstruct this plant and increase the development, thereby providing power for disposal in the United States as well as in Eastern Ontario. The company offers to have this project made conformable to any scheme for the development of the river as a whole.

The next possible development is that at the Long Sault Rapids, where the possible head is variously estimated to be about 35 to 40 feet. This is the site near Cornwall, where the Long Sault Development Company, a subsidiary of the Aluminum Company of America, intended to erect its dams had not their charter rights been cancelled by the State of New York—a cancellation which was confirmed by the Supreme Court of the United States.

Descending the river, we have next, in a stretch of about 14 miles between Lakes St. Francis and St. Louis, three series of rapids: the Coteau, the Cedars, the Split Rock and Cascades. The Coteau site is the one for which the Power Development Company, Limited, has been seeking rights. Of this company the "Montreal Star" states:

"There was incorporated, by letters patent a modest company, with a capital of $500,000, the incorporators being the bookkeepers of a well-known law firm in Montreal, closely associated with certain existing companies. . . . . A modest notice appeared in an obscure newspaper with a small circulation . . . . . and there was quietly filed a declaration in the Registry Offices of the counties where the proposed development is to be made, indicating that no less a scheme is on foot than the building of a dam across the St. Lawrence River."

Reliable assurances, however, have been given that rights for this development cannot be obtained without full public notice and discussion when all interested parties will have the opportunity of being heard.

The Cedars Rapids Manufacturing and Power Company utilize at Cedars rapid a head of about 32 feet developed by means of a diversion canal some two miles long. The power house has been designed for an ultimate development of 180,000 h.p. This company exports some 65,000 h.p. to Massena, N.Y.

The Soulanges plant of the Civic Investment and Industrial Company is situated a short distance below the Cedars plant. Power is obtained by tapping the Soulanges canal. The head is 50 feet.

The St. Timothee plant of the Canadian Light & Power Company is on the south side of the St. Lawrence directly opposite the two last mentioned developments. The water is led through a portion of the old Beauharnois canal.

I shall omit description of some other smaller plants, such as those at Mille Roche and in the vicinity of Morrisburg.

To summarize, we may place the estimated low-water power of the international portion of the River St. Lawrence at about 800,000 h.p., of which Canada is entitled to one half, or 400,000 h.p. The potential low-water power on the portion of the river which lies wholly within Canada would be 1,400,000 h.p. This, with its share of power along the International Boundary, makes an estimated total for Canada of 1,800,000 low-water continuous horse-power. It is detailed in the following table.

Water-Power on the St. Lawrence River*

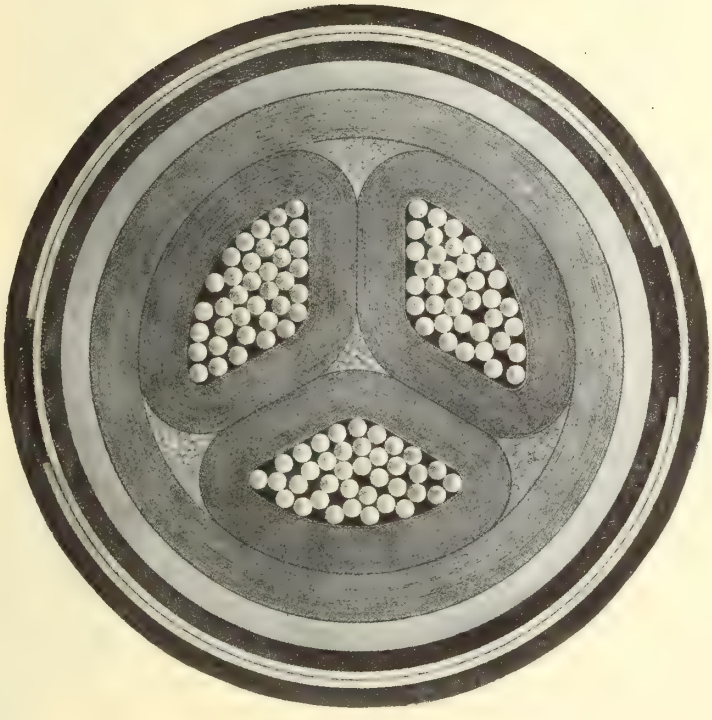
(Tentative schedule)

Site	Head available	Estimated low-water 24-hr. h.p.	Average estimated 24-hr. low-water h.p.
Morrisburg-Rapide Plat	11-15	170,000-230,000	200,000
Long Sault rapid	30-40	500,000-650,000	575,000
Coteau rapid	15-17	230,000-260,000	250,000
Cedars rapid†	30-32	490,000-525,000	500,000
Split Rock and Cascades rapids	14-18	220,000-280,000	250,000
Lachine Rapid	20-30	300,000-450,000	375,000
Total		1,910,000-2,395,000	2,150,000

*In this table, to have the estimates fairly representative of the possible quantities which might be expected under representative low-water flow conditions, some allowances have been made for efficiency and other factors.

†Under development for about one-third of the low-water flow of the river. Consideration would be given to the possibility of combining the Coteau, Cedars, Split Rock and Cascades; also of increasing the Lachine power.

The above estimate, excluding ice conditions, is conservative. Under a "diversity load factor," such as is experienced by the Hydro-electric Power Commission of Ontario, Canada's 1,800,000 h.p. would take care of a power demand of some 2,400,000 h.p.



Canada's share of this power belongs respectively to the provinces of Ontario and Quebec. The Federal Government has the rights in and jurisdiction over navigation. When the time comes for international questions in connection with the development of this river to be adjusted to admit of proper development, there is no doubt that the various interests involved, whether federal, provincial, corporate or private, will, respectively, be fully taken care of. Perhaps, for example, some arrangement may be made by which the Federal Governments shall provide the dams for navigation purposes, making available for each province its share of water-power under an arrangement by which the provinces would assume such financial and other responsibilities as were purely incident to the power assets.

I trust I have adequately emphasized the absolute necessity for statesmanlike dealing with our resources of boundary waters, the wise conservation, utilization and administration of which will help build up Canada and pay our future taxes.

Monthly Meeting of Illuminating Engineers

The executive committee recently appointed by Toronto illuminating engineers have secured the promise of Lieut. Oliver, of New York City, to address them on Tuesday evening, December 3. His subject will be "Artificial Daylight." Lieut. Oliver will outline the results of a series of recent experiments which, it is understood, go a long way toward the solution of the problem of producing a good northern daylight twenty-four hours of the day. The meeting will be held in the MacLean Building at 347 Adelaide Street West. All those interested in better lighting are requested and urged to be in attendance. The meeting is called for 8 o'clock sharp.

Now Then—What About Christmas?

IT is a pretty safe bet that nearly everybody is trying to spend his money these days as economically and efficiently as possible. None of us are exactly going out of our way to get rid of the coin and not a few of us are denying ourselves all pleasures and some necessities.

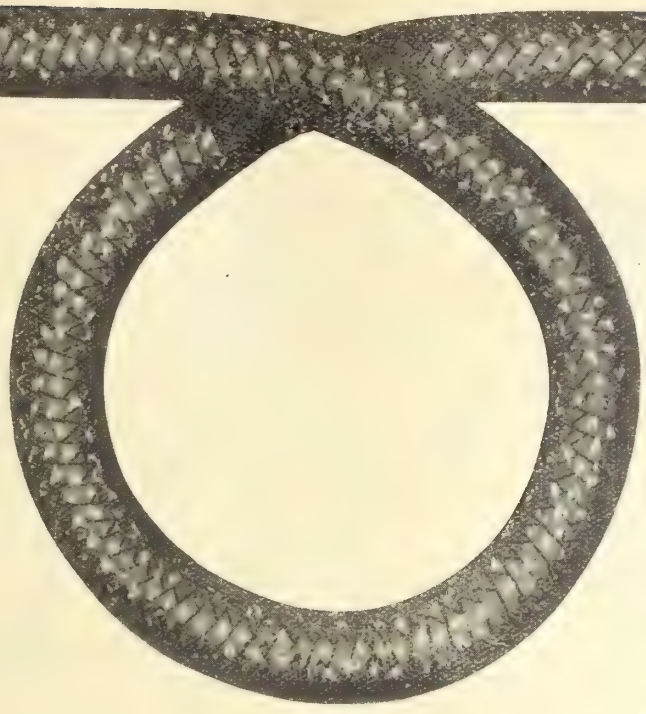
And now, right along comes Christmas. What are we going to do about it? Shall we make presents as usual? If so, what kind?

In our economies of living, some voluntary and others by Government regulation, we have found that lots of things we thought necessary to our existence are very easily dispensed with. Also that there is more satisfaction in spending our money on sensible articles than on flub-dubs and French pastry.

Most certainly we're going to give Christmas presents this year—one might just as well try to empty the ocean as to subdue the Christmas spirit of giving. But our Christmas presents this year, perhaps more than last year, are going to be in keeping with our established mode of living. They are going to be practical, useful gifts that will arouse in the recipient more than a mere passing sense of interest. The jim-cracks and the nick-nacks are going to be more than ever out of style.

It follows, "as the night the day," that nothing could be more consistent or worthy during our present economical and systematic living than electrical appliances. They are 100 per cent. useful, sufficiently ornamental to be pleasing and give lasting satisfaction. Moreover, electrical gifts can be chosen suitable for all ages from the little tot to the elderly totterers.

Further, the retailer who holds off until the last moment with his Christmas campaign this year and tries to send it off with a bang during the last week, is very likely to find himself among the "also-rans."



The spirit of early buying is abroad, and the electric retailer must take advantage of it. Don't lose another minute; make your slogan —"Buy early to relieve congestion; buy electrics to relieve worry and fatigue."

Electrical dealers, get your campaign under way. People are going to buy at least as usual. No one can give better value or satisfaction than you.

Sell Electrical Gifts for Christmas

The illustration above suggests big possibilities in the way of Christmas advertising.

Kraft Cord "Braiduct"

Made in Canada under Canadian Patent No. 147,057

This cut is reproduced from an actual photograph, and illustrates the behavior of the material in this rigid test—perfect flexibility. We cut the ends to show plainly the superior construction—note the high grade Canvas Duck Lining and the KRAFT CORD winding. This KRAFT CORD is made to our own specifications and is fire-proofed, which is entirely new.

KRAFT CORD "BRAIDUCT" is in a class by itself—superior to any imported conduit—is absolutely the last word in flexible non-metallic conduit construction.

We are now making our own insulating compounds, consequently every lot will be uniform in flexibility, and every foot is fished at the factory.

KRAFT CORD "BRAIDUCT" is easy to instal—easy to cut—easy to secure, as it is made in our own country, and easy to buy, as our price is right.

KRAFT CORD "BRAIDUCT" is packed in heavy fibre boxes, each box containing four coils (1,000 ft.), insuring product against damage in transit.

KRAFT CORD "BRAIDUCT" is regularly inspected and labelled by the **Underwriters' Laboratory** under the direction of the **National Board of Fire Underwriters** and every coil carries their label.

We will be glad to send you a sample.

The Flexible Conduit Co.

Limited

Guelph - Canada

Daum Refillable Plug Type Fuse

The illustration herewith shows a new refillable plug fuse manufactured by A. F. Daum. This is made of porcelain, the only metal being the fuse strip which is readily inserted afresh when a fuse is blown. The company state that the Oriental Electric Industrial Corporation, of Hagoga, Japan,

have just completed negotiations for a sole license in Japan, under the Daum patents. Mr. S. Mori, chief engineer for the Corporation, was recently at the Daum plant getting details, and stated that hitherto all fuses have been imported, and that the company he represents will be the first to make renewable fuses in the far East.

Victoria Electric Supply Co. Change of Address

The Victoria Electric Supply Company, jobbers of electrical supplies and fixture parts, announce that they are removing their business from 157 King Street, West, Toronto, to the ground and first floors of the Nordheimer Building, 77 York Street, just south of King. The new premises are very commodious and will admit of the more expeditious shipment of goods and also will enable the company to carry a more extensive stock of supplies. It is their intention to add to their lines a varied assortment of glassware and a complete line of automobile accessories.

Personals

Mr. Stanley Ebbett, of the New Brunswick Telephone Company at Moncton, has been appointed superintendent of traffic with headquarters at St. John.

Mr. F. T. Atkinson, district superintendent for the New Brunswick Telephone Company at Fredericton, N.B., has been transferred to Moncton, succeeding Mr. Stanley Ebbett.

Mr. Frank Harris, formerly exchange manager for the N. B. Telephone Company at Sackville, N.B., has been appointed district superintendent with headquarters at Fredericton.

Mr. C. F. Sise, general manager of the Bell Telephone Company, has been elected vice-president of the company, in succession to the late Mr. C. Cassils. He has been connected with the telephone business during his entire commercial life. After graduating as B.Sc. from McGill, he took up the study of telephone engineering; was later made superintendent of toll lines of the Bell Telephone Company, and in 1903 was appointed assistant superintendent of the company. Three years later he was made general superintendent, and in 1911 general manager. His present title is vice-president and general manager.

Messrs. F. H. Phippen and H. W. Harper have been appointed arbitrators in the matter of the demands of employees of the Toronto Street Railway Company. Mr. Phippen will represent the company and Mr. Harper the men.

Current News and Notes

Fredericton, N.B.

The New Brunswick Telephone Company have completed a long distance line between Fredericton and Minto.

Grand Forks, B.C.

A tram line will be built at the Rock Candy Mine, Lynch Creek, to connect with an extension of the Kettle Valley line a couple of miles above Lynch Creek. The new line will be a mile and a half in length.

London, Ont.

The city of London, Ont., recently applied to the Dominion Railway Board for permission to charge the Bell Telephone Company a rental of 25 cents for each pole or foot of underground conduit used in that city. The Railway Board stated that the matter would require parliamentary legislation and as the Bell Telephone Company would likely oppose the measure very strenuously, it is not likely that London will carry the subject further.

Montreal, Que.

The Shawinigan Water & Power Company have under consideration the development of Gres Falls, on the St. Maurice River. This water power was purchased from the Union Bag & Paper Company, of New York.

With a capital of $20,000, La Minoterie Moderne, Ltd., has been formed to take over the business of Laurin and Frere, Charlemagne, P.Q., and to develop water powers in the counties of L'Assomption, Montcalm, and Joliette.

The Dominion Bridge Company, Limited, Montreal, has received an order for two 5 motor, 40 ton capacity, 60 foot span electric travelling cranes from the British America Nickel Corporation, Limited, at Sudbury, Ont.

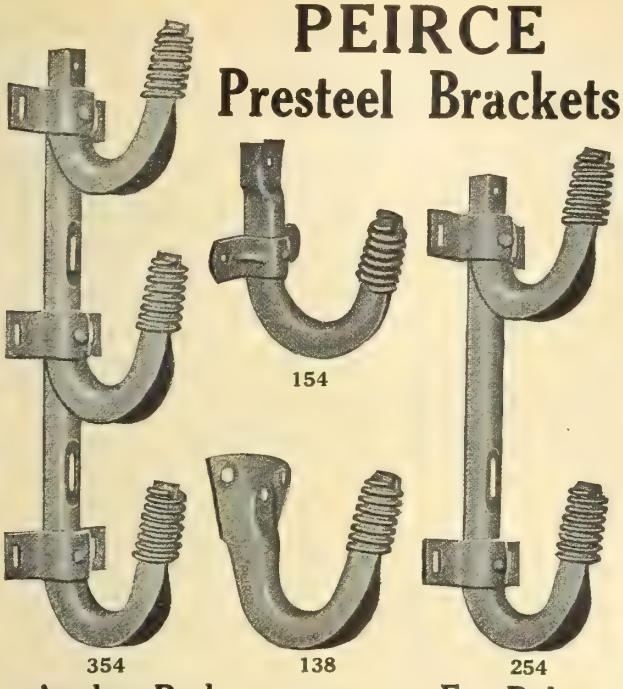
Ste. Anne de Bellevue, Que.

The Public Works Department, Ottawa, have awarded the contract for the construction of a light and power transmission line at St. Anne de Bellevue, P.Q., to the Artistic Brass Works Company, 250 Beaver Hall Hill, Montreal. The line is in connection with a group of military hospital buildings recently erected. The price is $5,500.

St. Thomas, Ont.

It has been definitely decided that the track and equipment of the London and Lake Erie Transportation Company will be scrapped. The city of St. Thomas will be paid $3,700 in settlement of back rental for the use of the city's tracks and will allow the company to continue using the tracks for hauling material until they cease operating.

Sherbrooke, Que.



The city of Sherbrooke, Que., has put into operation a new transmission line from Weedon to Sherbrooke, thus adding about 1,000 h.p. to the current available for manufacturers. The city purchased the property of the Two Miles Falls Power Company, installed new transformers and built the transmission line now in operation. A second unit is being installed at Weedon.

Toronto, Ont.

In accordance with an order by the Ontario Railway Board the Toronto Street Railway Company have taken on about 300 new men and have added about 175 more cars to the service. The Railway Board has ordered the company to place in service every available car.

Electrical workers in Toronto and vicinity, who are said to be now 90 per cent. organized against 40 per cent. seven months ago, are at present negotiating with employers for a new wage schedule, The union and employers, it is understood, are completely harmonious.

Motor For Sale

We have [illegible] for immediate delivery one [illegible] H.P., 3 phase, 60 cycle, 550 or 2200 volts, 600 R.P.M. Westinghouse form M [illegible] type, squirrel cage induction motor, [illegible] starting coil and oil switch. This motor is designed for direct connection, [illegible] equipped with special wooden pulleys [illegible]. The motor has been entirely re[illegible] and is as good as new. For further particulars write or wire Railway & Power Engineering Corporation, 203 C. P. R. Bldg., Toronto, Room 10, Windsor Hotel, Montreal. 23

Electrical Contractors Appliance Manufacturers

A [illegible] would join now or established business of 17 years electrical experience. Installation, [illegible] sales and factory management. Would purchase interest in good proposition.

W. HERBERT TEES,
23 Box 326, Ingersoll, Ont.

How Pennies in the Mail Sold Irons

You've got to hand it to the ladies! The following letter was received by the Westinghouse Company from Miss J. A. Kerkhof, Manager of the Seymour, Indiana, Store, of the Interstate Public Service Company:

"We are in receipt of some little booklets and folders from you which we consider the most attractive and valuable advertising helps. Please find enclosed sample letter which we are sending out to a number of iron prospects with which we are using your booklets."

With this letter came a small envelope, just the proper size for enclosing folder, "Labor Savers for the Home," for that is the little booklet referred to by Miss Kerkhof. And in each envelope with the folder was a brand new penny. Accompanying this envelope with its folder and penny was a letter that drove the penny right through the folder and into baby's bank, but not without bringing the desired results:

"A bad penny always returns," says the letter, "but this is not a bad penny, and we don't want it returned. Keep it for luck, or put it in the baby's bank." That's the introduction to the penny and then the letter states that the penny was sent for two reasons, one to pay for reading the letter and the second to bring to the reader's attention the tremendous power back of the penny. How two of these little pennies each day would pay for an ironing and how simple it was to secure the iron by phoning Miss Kerkhof.

And when the call came over the phone she got there in a hurry. That is one of the ways she has placed 725 irons in the homes of 890 residence consumers. Of course, Miss Kerkhof knew what the ladies in Seymour were missing by not ironing electrically and she didn't add much to their pleasure until she had them persuaded.

But we just have to hand it to the ladies these war times, and we take our hats off to Miss Kerkhof with 725 irons out of 890 possibilities.—In "Contact."

The Chief Benefit

derived from

"No Spark"

CARBON BRUSHES

IS FREEDOM FROM TROUBLE REPLACING AND RESETTING BRUSHES. Being self-lubricating, they make the contacts practically frictionless and reduce commutator repairs enough to pay for themselves several times over. With these carbon brushes, the machine runs noiselessly without any sparking. These are facts which you can at once prove.

Write for our latest Bulletin

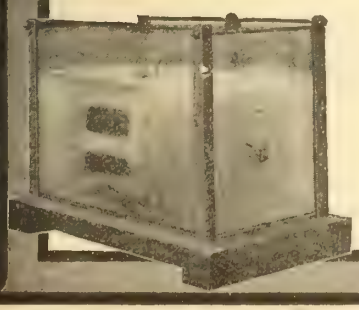
NOTICE

To Manufacturers and Others

We are not only builders of the famous Lincoln Arc Welder, but we are also in a position to quote you on welding and repairs to your machinery or boilers. We have complete equipment for this work and can have our plant brought to the job on short notice.

We keep a staff of operators ready for any emergency.

Let us quote you on your welding and save many dollars on machines that you would otherwise scrap. A phone call will bring a man in a hurry.



You can save 50 per cent.—very often more—by doing your boiler plate work with a Lincoln Arc Welder instead of rivetting it.

Lincoln-welded joints are 100 per cent. strong—rivetted joints are no stronger than the rivets themselves.

It has been adopted by boiler shops, structural steel works, street car and railroad companies as being the most practical solution of the present labor shortage.

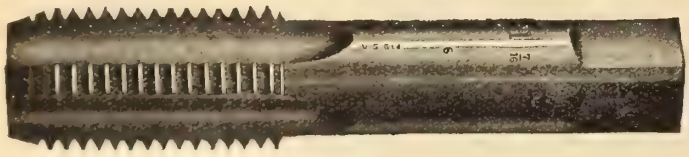
GROWTH—

Day after day, week after week, month after month, for the five years that Economy Fuses have been on the market, the sales have maintained a constant growth—not alone in volume, but also in percentage of increase. This is because



ECONOMY Renewable FUSES

are absolutely accurate in operation and cut annual fuse maintenance costs 80%. An inexpensive little "Drop Out" Renewal Link restores a blown Economy Fuse to its original efficiency.

Walger Insulated Wire Connector

Solderless Connection

Insulating Shell and Cap

Patented Canada 1917.
Patent Pending U. S.

DISCARD THAT BLOW TORCH

Just think—no blow torch to explode or blazing alcohol to boil over, no injury to canopy or ceiling on account of smoke, no setting fire to wall covering, etc. with blow torch, no dropping of hot solder, burnt matches, bits of tape or soldering acid, paint work or walls not marred by dirty hands, no tools to fall from ladder, no time wasted going from one fixture to another, one trip up the ladder is sufficient.

All you require to make the connection secure is a screwdriver.

The Walger Insulated Connector is so simple in construction that it is impossible to make a mistake in making a connection. In other words, it is wonderfully simple and simply wonderful when you see it in use.

The Walger Insulated Connector is one of the most profitable electrical accessories you can handle. Write for further information.

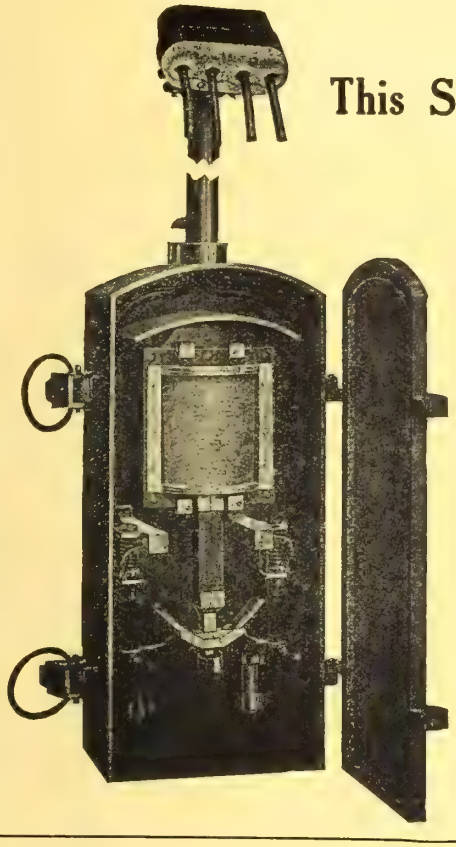
Electric-Arc Welding

Westinghouse Arc Welding Motor-Generator Equipment

The flexibility of Westinghouse Electric-Arc Welding Equipments allows the quick execution of a wide range of repair jobs, not possible by other methods.



It is designed with a view to the utmost simplicity, avoiding complicated control devices, so that the ordinary mechanic can use the equipment with ease and safety.

Our Leaflet 1826 gives full details.

Canadian Westinghouse Co., Limited, Hamilton, Ontario

Toronto	Montreal	Ottawa	Halifax	Ft. William	Winnipeg	Edmonton	Calgary	Vancouver

This SOLENOID SWITCH has been adopted by the Hydro Electric Commission

They use it for

STREET LIGHTING

Now the fact that it is used by the Hydro-Electric Commission is proof that it is all we claim for it. It certainly is not an experiment, by the fact that it is giving efficient service in many towns throughout Ontario, as well as the other provinces.

No springs, swivels or other complicated mechanisms to give trouble. They close magnetically and are opened by gravity assisted by the tension of the laminated copper contact. All arcing is taken up on the carbons.

Increase the efficiency of your system and decrease the cost of installation by using our Type 17 H.E.P. Solenoid Switches, which are suitable for any frequency on multiple circuit or D.C. Series circuit.

G&W ELECTRIC SPECIALTIES

Reduce Distribution Troubles and Expense

in these Five ways—

—Equip to handle "trouble" without costly cable or line cutting.
—Eliminate expensive "temporary" repairs.
—Install cable-end sealing devices.
—Stop extended service delays.
—Make every circuit interconnecting without cable or line cutting.

IT is the purpose of G & W distribution specialties to obtain maximum distribution **economy** for a minimum of **cost**—it is the purpose of G & W Engineering Service, with 15 years' experience for a working back-ground, to see that you **do** get just that.

Nowadays **preventable** waste is almost the same as deliberate destruction. G & W distribution specialties plus G & W application service can help you eliminate many costly, untimely distribution troubles. Ask us for the solution of your most troublesome distribution problems!

Have you received new Catalog No. 10? Contains Valuable illustrations and drawings for every Central Station Engineer

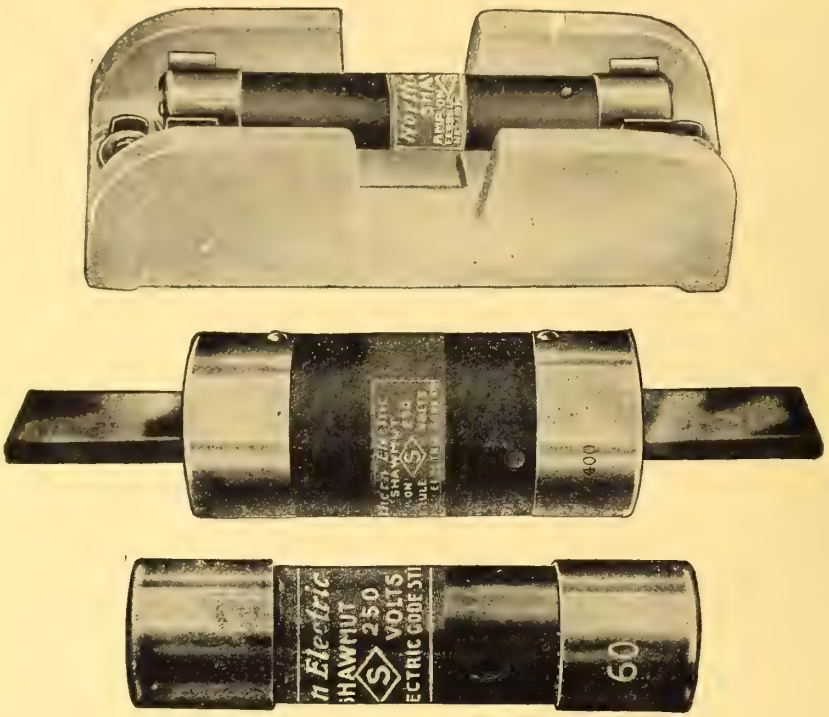
Electrical News

Generation, Transmission and Application of Electricity

A Quarter-Century of Continuous Production

Since Vitreous Enamel Insulation was first developed by Ward Leonard, upwards of twenty-five years ago. our furnaces have been in continuous production without even a twenty-four-hour idle period.



Such a record is some indication of the high calibre of Ward Leonard Resistance units, and Resistance Plates, the resistance elements of which are permanently sealed by Vitreous Enamel Insulation against any service deterioration.

"FLEXTUBE"

FLEXTUBE

The seamless, interwoven and non-collapsible construction of FLEXTUBE, the quality of the materials which enter into its construction, the "roller-bearing" wireway, the double compounding and the protecting outer braid, make this a distinctive product, one which pleases the wiremen, increases the profit of the contractor and gives eminent satisfaction to the owner.

Your use of FLEXTUBE, or examination of a sample (sent upon request), will verify every claim we make for it.

Absorbs the Shock

Our special C. & H. Poly-Phase Meter is safe because it is fitted with new double terminal blocks that absorb the shock and reduce the danger of accident resulting from overloaded wires and from surge conditions during lightning storms.

This meter also has more inside room for the connections, and the three or four lines are carried straight through the meter from the left to right. In every respect this C. & H. Poly-Phase is a Safety Meter, and is undoubtedly the one to select for Installation on Long Distance Transmission.

C&H Poly-Phase The Safety Meter

The Company's guarantee goes with every instrument. The new Poly-Phase is as near perfect as it is possible for a meter to be.

THE "TYPE S" PORTABLE WHEATSTONE BRIDGE

Useful in the Shop and Laboratory for the Measurement of Resistance· Adapted for Fault Locations in Telegraph and Telephone Lines and Cables.

The Type S Bridge is a thoroughly practical instrument for shop and field use. Being complete in every detail it is ready at all times for immediate use. It is easily portable, its weight being but 8 pounds. The precision of adjustment of its coils (Rheostat 1/10 per cent., Ratio 1/20 per cent.) insures accurate measurements. The galvanometer, the weakest element of such an instrument, is unusually rugged. It is a separate element and may be removed for examination or repair by taking out two screws. The battery is of the ordinary "flash light" type, and renewals may be procured practically everywhere. The price is $66.25 net, f.o.b. Philadelphia, boxed for shipment.

Bulletin No. 530 describes this instrument.

The Final Touch of Quality

The manufacturer who makes a high quality washing machine, suction sweeper or other motor-driven device, selects his Motors with unusual care. He insists upon a motor fully in keeping with the quality of the machine he manufactures, a motor which will insure reliable, efficient service from his product.

This is the reason leading manufacturers of motor-equipped devices for the home, office, store and factory choose R & M Motors for their machines. Quality seeks quality just as naturally as water seeks a level.

Another reason leading manufacturers prefer R & M Motors is the fact that the quality of the R & M Motor is known to nearly all prospective buyers of their machines. A decade of dominant advertising in the principal national magazines has made the R & M Motor on any device a quality mark for the machine which nearly everyone recognizes.

The same factors which make it an advantage for the manufacturer to equip his machines with R & M Motors also make it an advantage for the dealer and central station to push devices so equipped. They insure reliable service for the user and the known quality of the motor helps make the sales.

Vol. 27 Toronto, December 15, 1918 No. 24

Are Canadian Members of International Joint Commission Sufficiently Alert to Dominion's Interests

In accordance with usual practice the International Joint Commission has published an opinion in support of its interim order in the St. Lawrence River power case, referred to in our issues of September 15 and October 1. This opinion was prepared by Mr. Justice Mignault of the Supreme Court of Canada, and outlines the history and scope of the application, describes the locality, analyzes the evidence submitted regarding the effect of the proposed submerged weir, and so on.

Treating first the jurisdiction of the Commission to deal with this matter, the report advances a number of arguments from which the conclusion is drawn that "this sufficiently disposes of the objection that the Commission is without jurisdiction, which objection, in the opinion of the Commission, is groundless."

Referring then to the matter of a decision regarding the erection of the weir itself, Mr. Justice Mignault notes that too short a period of time was allowed in which to consider the matter from all sides. "A sudden emergency," he said, "had arisen," and he argues that the order is so framed that "no rights of either country or of any of its citizens can possibly be jeopardized by its action" since "the submerged weir is approved 'merely' for a term of five years or until the duration of the present war, whichever shall last occur." He does not think there is any ground for the fear expressed by Hon. Mr. Guthrie, that "if it goes in it will never come out," although doubtless Mr. Justice Mignault is fully aware of the conditions existing, for example, at Niagara Falls, where the cry of "vested rights" in the United States has made it impossible to recall electricity developed on the Canadian side and exported to the States, though the exigencies due to war demands have made it just as urgent, doubtless, as have the requirements of aluminium for which the weir in question is being constructed.

There is one point too that Mr. Justice Mignault seems to almost studiously avoid. That is the fact that the work for the weir was well on towards completion before any application was made to the Joint Commission. This fact is called attention to in a paper by Mr. A. V. White, printed in our issue of December 1, in which he used these words:

> "The St. Lawrence River Power Company is a subsidiary company of the Aluminium Company of America, which, amongst other activities, operates a large aluminum-producing plant at Massena, N. Y. The St. Lawrence River Power Company desired to construct works in the St. Lawrence which would, so far as possible, remove ice difficulties which affected their winter output, 25 feet deep by 150 feet wide, in the bed of the St. Lawrence River. Complementary to this excavation there was to be a large boom held by rock-filled cribs, some 30 feet square, sunk in the St. Lawrence River. Below the dredged channel just referred to, there was also to be constructed in what is known as the South Sault Channel—that is, the passage nearest the United States shore—a 'submerged weir,' which actually is a large submerged dam. **The work of channel excavation was undertaken and practically completed** under permit from the United States War Department, **without the matter in any way being brought to the official attention of the Canadian authorities."**

If the jurisdiction of the Joint Commission covers this matter, why were they not awake to the fact that treaty obligations were not being observed by the United States? Surely this Commission is very much to blame that a work of this nature could go on without their having knowledge of it.

As it turns out, the war is over before the weir is completed and the Commission have merely given the St. Lawrence Power Company a gift, for five years, of whatever advantage the weir may prove to them in developing their industries. Surely there is a limit to liberality.

On both these counts we cannot see but that the Canadian members of the Joint Waterways Commission were guilty of being over-ruled, (perhaps over-awed), by the powerful interests against which they were supposed to be contending for Canada's interests.

Canadian Reconstruction

The Canadian Reconstruction Association, Sir John Willison, president, are publishing a number of valuable pamphlets on various phases of reconstruction work, one of the most valuable of which deals with the organization preparations that Great Britain is putting forth.

Organization, co-operation and combination are the guiding principles in the remarkable preparations which Great Britain is making for reconstruction. In the industrial, commercial and financial world the common impulse is towards the close association of banking, trade and business interests. A new industrial machinery is being created, so constructed that Great Britain will be able to maintain and improve its commercial position in the face of intense and highly organized competition.

The United Kingdom is considering changes in economic policy which may have far-reaching influences on world affairs. It is correcting surely the mistaken policies of the

which left it dependent upon other countries for essential commodities. Not only are new basic industries being established. The impetus lent to land cultivation by government and public activity has gone far to correct the dependence of the United Kingdom upon other countries for foodstuffs. It is estimated that for this year sufficient food will be produced to feed the population for 40 weeks as against provision for 10 weeks before the war. The area under wheat is now one and a half times what it was in 1914. The supply of home grown cereals in 1917 was more than 850,000 tons greater than the previous year, and the potato crop showed an increase of 3,000,000 tons. By the middle of February this year some 1,200,000 fresh acres had been brought under the plow in addition to the fresh acreage recorded in 1917. At the end of May, the Director-General of Food Production for England and Wales published an interim report on the result of the year's campaign for increasing home grown supplies. It estimated that the area of land under corn crops this year in the United Kingdom will be more than four million acres greater than that of 1916, and that the acreage under potatoes in England and Wales alone will be 50 per cent. larger than in 1916. Both these figures would constitute a record in the history of British agriculture. They do not take into account the produce of allotments and private gardens, of which the former have increased in England and Wales by not less than 800,000 since 1916. Much of the greatly increased production is due to the work of women; 316,000 being employed on the land, of whom 300,000 are village women, and 16,000 in the land army. Indeed, not only agricultural but industrial and national life have been effected by women war workers who are now estimated to total 4,500,000, of whom nearly 1,500,000 are doing men's work. No fewer than 1,000,000 are employed on munitions, while many thousands are to be found in banks and financial institutions, stores, shops, railway employment and other occupations.

The pamphlet deals with various phases of industrial life under the following headings:—industrial policy, raw materials, combination urged, greater markets, general trade policy, export trade plans, metal bank authorized, organization of reconstruction committees, scientific research, bank amalgamations, fiscal policy, necessity for tariff, protection advised, imperial preference.

This is the first of the series to be issued by the Canadian Reconstruction Association, dealing with measures being taken in other countries to meet after-war conditions. The signing of the peace agreement will undoubtedly be followed by a period of intense commercial rivalry. In Great Britain, the United States, France, Japan, etc., co-operation and combination are the guiding principles of the preparations which financial, industrial and business interests are making with their governments for the coming trade struggle. It is essential that like preparations and like co-operation should be pushed forward in Canada without delay.

Montreal Electrical Luncheons

Mr. W. G. Mitchell, described the natural resources, climatic characteristics and trade possibilities of Siberia at the Montreal Electrical Luncheon, on November 27. Siberia is just now in the public eye and Mr. Mitchell, who has just returned to Montreal, after two years in European and Asiatic Russia, was able to give a large amount of information as to that comparatively little known country. He remarked that the natural resources and physical features were almost identical with those of Canada, but there was this great difference —Siberia had no water powers, so that hydro-electric developments like we possess are impossible. The climate was perhaps a little more severe than in Canada; the summer temperature averaged 70 degrees and sometimes went to 105 degrees, and in winter the average was 10 degrees below zero.

There were no limits to the mining possibilities, the deposits of coal, copper and gold being enormous. Lumber and fur were also great assets; the country had very large supplies of pine, spruce maple, birch, walnut and oak. In his opinion Siberia has a fine future—its possibilities could not be exaggerated.

"Electricity and Surgery" was the subject of a talk by Dr. G. Fisk, at the Montreal Electrical Luncheon, on December 4th. It was a most informative speech, touched with incidents which had come under the doctor's observation. He referred to the great landmarks in the history of surgery, the discovery of anesthetics, the antiseptic and aseptic treatments, and the last, the important part which electricity was playing in surgery. In this connection Dr. Fisk alluded to the use of the X-rays in diagnosis, and also described the mercury vapour lamp, which was being used in sterilizing the skin, in skin diseases, in improving nutrition, curing rodent ulcer, and in cleansing infected wounds. The ultra violet rays, X-rays, and radium rays stood in the order named as regards intensity, and here, as in the case of the Hertzian waves, there were vast fields for investigation by electricians. Electrical heat was also being extensively employed in surgery. Massage had come into its own during the war and should be employed in combination with electricity.

Dr. Fisk concluded with a consideration of what he termed the greatest force of all, the electro-magnetic force of human personality, which was so freely cultivated in the East. Western men had the faculty of devising machinery, but little skill in cultivating the mental power.

Britain's Effort in the War

On Friday, November 6, the Electric Club of Toronto, was honored by having as its guest and speaker, Hon. Dr. Cody, Minister of Education for the Province of Ontario, who has recently returned from a visit to the Old Land and the battle-fields of France and Flanders. Dr. Cody spoke on Britain's effort in the war, and seldom, if ever, we are sure, has the club listened to as inspiring or gripping an address.

There was no need for apology, said Dr. Cody, for speaking to a group of electrical men on the subject of war, for the war could never have been waged as it has been without electricity. The development of artillery fire to its present efficiency and its co-ordination with infantry advance would have been impossible without electricity. By its use the headquarter's staff is advised, within a few minutes, of the happenings up and down the line. The submarine is directly the result of electrical appliances. And so, from the motor lorry up to the aeroplane, we find that electricity has played a tremendous part. Indeed, the present struggle is a warfare of gasoline and electricity.

Dr. Cody said he would not stop to speak of the achievements of the Canadian corps, except to say that it was excelled by no corps on the Western front. Everywhere, too, Canadians were found occupying places of distinction in other British armies. Col. Chas. H. Mitchell was possibly the best intelligence officer in the whole army. Col. W. G. MacKendrick had won himself high distinction as a road builder. Gen. Ed. Morrison, of Ottawa, formerly a newspaper man, was one of the foremost artillery officers on the western front, as was also Professor McNaughton, of McGill University, who, it was said, had been instrumental in practically revolutionizing artillery practice in that field. General Ross, of Kingston, a medical man, was offered the position of Chief Medical Director of the Fifth British Army. And so, everywhere, Canadians were holding positions of honor.

But it was of what the old Mother Land had done that he wished to speak, because there had been most insiduous propaganda on this continent that England would fight to the last Canadian, or to the last Australian.

The effort of the Motherland could be divided into three elements—the effort of the army in the field, the effort of the army at home, and the effort of that power, so salient and seemingly remote, but at the same time omnipotent, the British navy.

Regarding the British army, it was interesting to note that 75 per cent. of the total was supplied from the United Kingdom, while 12 per cent, came from the Overseas Dominions, and 13 per cent. from India. When we begin to analyze the contribution of the United Kingdom, we find that England gave 60 per cent., Scotland, 8 per cent., Wales, 3 per cent. and Ireland 2. So in point of the number of men who have borne their part in the struggle, the Motherland has given her share. Leaving out India, and including only white troops, there came from the United Kingdom 85 per cent. of the men raised and the casualties were 86 per cent. of the total, while we overseas recruited 15 per cent., and our casualties were about 14 per cent. Therefore it is not fair to say that England would fight to the last Canadian, when one thinks of the army she raised—up to the end of 1917, seven and a half millions, and up till August, 1918, eight and a half millions. That army at the beginning was small, but that little force of 160,000 men was the most highly trained in the world; none were so perfect in discipline and endurance. It was by a wonderful feat of transport that they were landed in France in two weeks. Eighty thousand of them were thrown in at Mons against two German army corps, later augmented by three additional army corps, and supported by innumerable artillery. They were out-numbered and out-gunned and they had to retire, fighting grimly all the way. At Le Cateau, they fought a rear-guard action under General Smith-Dorrien and gave the Germans a beating, making it possible to retreat in good order to the Marne. It was the endurance of that little British army that made the victory of the Marne possible. At Mons, too, the British army won glory enough to last for an eternity, but no more was said about it in the British papers than might have been said about a sham battle on Salisbury Plains. Then there was the first battle of Ypres in the terrible Ypres salient, perhaps the worst part of the whole western front, and in that winter the first British army held the Germans while Kitchener's first hundred thousand were in training, against tremendous odds, fighting at times spaced ten to twenty feet apart. "Do not, on this continent of effervescence and advertising, let us misunderstand what the race from which we are sprung has done."

Wide Scope of British Activities

British troops have carried on campaigns not only in France and Flanders, but in Italy, in Egypt, in Palestine, in Mesopotamia, in the Balkans and in Persia, and at Archangel, too, they landed a force to save from the Germans and the Bolsheviki, stores which rightly belonged to the Allies, besides the operations which conquered the Germans in East and South-West Africa. All over the world the British army has waged its conflicts, sometimes, indeed, with reverses, but while Britain may lose battles, she does not lose campaigns. The battle she always wins, historically, is the last battle, and and if the armistice had not been signed at the time it was, the whole Geramn army, practically, would have been forced to surrender, but Foch did not cherish the desire, or at least, did not urge the point to win the most brilliant and striking victory in the field in the long course of miltary achievement. He gave up that victory that he might spare the lives of his men, when he secured the same result in a less costly and spectacular manner.

The army in the field was made possible by the army at home. First of all Britain found that she was hopelessly unprepared in guns and munitions. We were firing shrapnel until May, 1915, when it was found that only high explosive shells would do the work. Then Lloyd-George took hold of the Ministry of Munitions, reorganized it and put some of his own energy and enthusiasm into it. That was the turning point of the war on land; government arsenals multiplied apace, private concerns all over the country took up the manufacture of munitions, and controlled industries in which the government was a partner increased a hundred fold. Perhaps the most marvellous of all the plants created was that at Gretna Green, the largest cordite factory in the world. This whole plant, including two towns within its confines, extends for a length of about ten miles, and of its working force, possibly 90 per cent. are women and girls.

How was this triumph attained so that Britain had shells enough and to spare. It was the British genius for organization—a genius of which we thought Germany had a monopoly—the biggest mistake we ever made—that made it possible in the first place. The other explanation was the spirit of the British women. Women of high degrees and low degrees and no degrees at all, went in and worked like daughters of Titan, carrying out operations of which one could not have believed them capable.

And as to finance, Britain, in the first year of the war, financed her overseas Dominions to the tune of one billion dollars, and she has financed her allies on the continent to the extent of eight or nine billions. Her war debt, when all is over, it is estimated, will be 50 billions. When her debt

[illegible] she had raised 25 or 26 billions by loans, and 4 billions by taxes. Britain has been paying taxes that would make us turn pale or shoot the tax collector.

How what about the ration? Her people endured the most rigorous ration that there might be space in British ships for American troops. The pasture land, much to their disadvantage, was used for the production of wheat that France and Italy might be fed. Fifty per cent. of France's coal supply came from Britain, and she lent to France one million tons of shipping. She was the carrier, clothier and universal provider of her continental allies.

The Grand Fleet

Then there was the third great contribution that Britain made. Dr. Cody said that even after he had been all the way through the five British armies and had seen the great munition plants and aerodromes, he still felt that there yet remained the climax of it all. So he hied him to the old city of Edinburgh and down the Firth of the Forth, and there he saw stretching for twenty-five miles out to sea, the Grand Fleet. We cannot reproduce in print the word-picture which Dr. Cody drew of this great sight. There were the mighty super-dreadnaughts, like the Queen Elizabeth, Admiral Beatty's flag-ship, and the Iron Duke, which had been Admiral Jellicoe's flag-ship; there were the Malaya and the New Zealander, which had been contributed by the countries of which they bore the name; there were battle-cruisers, like H.M.S. Lion, which had been battered in the Jutland fight; there were newer and lighter battle cruisers, which had sacrificed armament for speed—ships whose bows cut the waves like razors; and there were the indomitable little destroyers. At such a sight, one thought of what sea power had meant to the world, of how empires had fallen when they had lost control. One thought of the Armada, and of Napoleon, and then of him—what shall we call him? —William the Last. On every occasion it was sea power that counted most, and so far as Europe was concerned, it was British sea power that kept the ocean free. This has made it impossible for German battleships to prey on the commerce of the world, has made it possible for 20 millions of British troops to be conveyed, back and forth, to the battlefields. This was the fleet that was responsible for the carrying of supplies, which baffled the German effort to choke the Allies by her submarine warfare, which convoyed two million Americans to the battle area. It was the fleet that sounded the knell of German domination. Britain held her dominion on the seas and by the seas, said Dr. Cody, and she will not, please God, forego her right and her privilege to maintain her supremacy on the sea. For "The sea is His and He made it," and can we not reverently add, "and Britain has kept it free."

Another Big Night for the Toronto Section of the A. I. E. E.

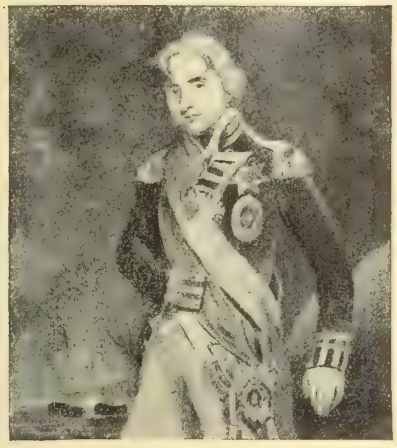
More than one hundred and twenty members and friends of the Toronto Institute of Electrical Engineers attended a meeting at the University of Toronto on Friday, December 6, to hear an address by Dr. Saul Dushman. Not only did the Toronto membership turn out in force, together with a number of professors and students of the School of Practical Science, but at least half a dozen ladies were present, attracted by what proved to be a most fascinating address delivered in inimitable style. Dr. Dushman selected for his subject 'Some Recent Applications of the Electron Theory," and although his main intention was to deal with the development of the kenotron and other hot cathode apparatus, he began his talk with a resume of the whole field of vacuum and Rontgen tube research, which has occupied such advanced scientists as Crookes, Thomson, Ramsay and others. Great improvements in the means of exhaustion have provided much greater degrees of vacuum than the early investigators ever dreamed of, and at the same time the practical applications of the electron theory have been widely increased.

The kenotron is a vacuum tube having its cathode heated by a local battery circuit and has been used by the thousand by the United States Government for the equipment of aeroplanes as part of their wireless plant. The instrument itself provides a convenient rectifier and source of high voltage direct current. The well-known Cottrell process of smoke precipitation by electronic discharge employs a group of kenotrons as its power plant. Some photographs taken of a roundhouse of the P. & R. Ry. at Philadelphia showed in remarkable fashion the effect of this plant in clearing smoke.

The apparatus which Dr. Dushman brought up with him from the General Electric laboratory at Schenectady enabled a number of interesting demonstrations to be made which quite substantiated the laws believed to govern the current discharge from a hot cathode with different temperatures and voltages. Furthermore, many slides which were shown on the screen helped to make the treatment of the subject most complete and comprehensible to the layman.

It is a tribute to the importance of the Toronto Section that a physicist of Dr. Dushman's standing should take the trouble to make a six hundred mile trip in winter for the purpose of addressing a Section meeting. Nevertheless, electrical engineering is perhaps the most active and important profession in Ontario, and the suggestion that Canadian electrical engineers should have their own technical institute, which has been heard in several places, has been voiced not without reason.

On January 17, 1919, the next meeting of the Toronto Section will be held in the Engineers' Club, when the privilege of an address from Mr. Roland C. Harris, Chief Commissioner of Works, will again bring the members together. Commissioner Harris has promised to talk about civic engineering in general and some engineering features of "The Bloor Street Viaduct" in particular.



Coal Consumption in Electric Plants

The Hydro-electric Power Commsision of Ontario have issued a report on the rate of coal consumption in various electric generating stations and industrial establishments in Canada and the United States. The basic data for this research has been selected only from those relating to such electric power stations as use coal for fuel and which use it entirely for generating steam. Special effort has been made to eliminate all factors which would in any wise be irrelevant to the purpose in hand. Thus, all stations which, in part, use wood, oil or fuel other than coal; stations using producer gas and those employed for standby or auxiliary purposes, have been disregarded. Most of the figures given are averages for the past five years and average figures for different sizes of stations have been deduced therefrom. The report contains a quantity of tables, curves and charts.

Mr. J. E. Aldred, president of the Shawinigan Water and Power Company, states that they are closing the biggest year in their history so far as volume of business is concerned. While the actual figures have not been made public it is said they will be entirely satisfactory to the shareholders.

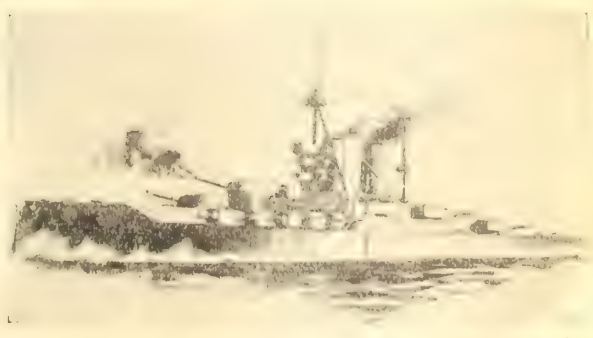
The Matane Lumber and Development Company, incorporated with a capital of two million dollars, takes very wide powers, including the acquisition in the counties of Matane, Rimouski, Gaspe and Bonaventure, P.Q., of water powers and the right to generate, distribute, and employ electric power.

1805 — 1918

Admiral Lord Nelson

HISTORY's greatest sea spectacle in 1918 came within thirty days of the anniversary of the world's greatest sea battle. Trafalgar was the world's greatest sea fight because it marked the coming downfall of one more despot of mankind. Napoleon failed to make Paris the Capital of all Europe because he never could invade England. The little guns that hurled cannon-balls from the "Victory" in 1805 were the fore-echo of the guns of Waterloo in 1815, and of the silent surrender of the Kaiser-navy 103 years later. Had Nelson never flung his fleet of wooden tubs from the forests of England at the ships of France and Spain, Wellington's great little armies might as well never have marched. We read that in the action at Trafalgar the four ships "Victory," "Temeraire," "Redoubtable" and "Fougeux" fought so close that they made almost a single deck. Sabre and musket, man to man they fought, and there was Nelson in the midst of them, as he always was. From the mast of the "Victory" still fluttered in the smoke the rags of that immortalizing signal, "England expects that every man this day will do his duty." When Nelson spoke in the name of England it was with a passion that not to obey him was not to know the glory of duty. Master of naval strategy and tactics, he never had time to write a book about it, because he was too busy fighting for England. He knew nothing of politics, like Wellington; nor of statecraft, like Napoleon. But he knew the swish of the sea, the roar of the guns, the coast-lines of Europe from the Baltic round to the Aegean; and wherever he went—after whatever enemy—sailor, daredevil fighter, poet in action, terrible and beloved, he carried with him like a song, "England, My England." Trafalgar was his last word to Napoleon that England must conquer because she could not be invaded.

"Mighty seaman, this is he,—was great on land as thou by sea," wrote Tennyson in his Ode to Wellington. A musket ball from the crosstrees of the "Redoubtable" killed Nelson. But the death of Nelson was the life of England and duty, as Trafalgar was the first sure sign in 1805 of the liberation of all Europe.



H.M.S. "Victory"

Admiral Sir David Beatty

THREE times in four years he had fought them. He had hoped to fight them again—and to a finish. But here in the North Sea, November 21, 1918, was the finish without the fight. Seventy-one Kaiser-ships of the line steaming up the lane of a great nation's navy. Five hundred great guns—any of them at ten miles could have riddled all Nelson's fleet of tubs in 1805—Never a shot! It was his answer to that day when the High Seas Fleet put to the North Sea in 1914 with the King's message. "Capture or destroy the enemy." Perhaps he remembered that twenty days afterwards; he potted five German cruisers off Heligoland; and then he began to wait, prowling in the fog, looking for more ships from Kiel—till on January 24th, 1915, he sank the "Bluecher" and smashed the "Seydlitz" and the "Derflinger" in that 100-mile run—back to Heligoland, when all the "Lion's" gunners had to aim at was a target of funnel-tops and smoke, the size of a threepenny bit. One year and three months more he waited; till May 31, 1916, when in the battle of Jutland the Rear-Admiral's Fleet came at the bulk of the Kaiser-navy that ran when Jellicoe's supports came up—back to Heligoland. Rear-Admiral became Commander-in-Chief and waited again; shuffling his great mystery fleet back and forth in Scandinavian mists, nobody unofficially knew where—till the morning of November 21st, 1918, he put to sea in the "Queen Elizabeth." What a sight greeted him! The dark-grey lines of the Invincible Navy in the smoke; the six-mile lane; the fog lifting; and out of the low mist from the region of Heligoland they came—abjectly to surrender!

It was "Der Tag" Dead March of the Kaiser-navy; more magnificent in its fitting humiliation to a degenerate race than any surrender of an army. Never a shot, nor a shell, nor a shout. In a great grey silence of miles of monster ships the Kaiser's ensign was hauled down and the sullen sea drama was over. Was Beatty happy? Heaven knows. Three times he had fought 'em, doing his bit to bring one more despot of Europe to his knees. He had hoped to fight 'em again. Here was the finish without the fight. What a finish!

H.M.S. "Queen Elizabeth"

45,000 Kw. Cross-Compound Steam Turbine

Separate High-Pressure (Single Flow) and Low-Pressure (Double Flow) Elements Each Coupled to Its Own Generator

There has recently been put in service in the Brunots Island power station of The Duquesne Light Company, at Pittsburg a 45,000 kw cross-compound turbine-generator unit which is described in the Electric Journal. The cross-compound idea is not new, of course, even in steam turbine practice, a most successful example being the three 30,000 kw. units which have been in operation for some years in the 74th street power station of the Interborough Rapid Transit Company, New York, while in the same power station has just been installed the largest turbine yet constructed, a three-cylinder, cross-compound unit of 70,000 kw. capacity.

This new 45,000 kw. Pittsburg unit consists of separate high and low-pressure elements, each coupled directly to its own generator. The high-pressure element is a single-flow, reaction-type turbine, running at 1,800 r.p.m. and expanding to atmosphere. The low-pressure element is a double-flow turbine of the same type, running at 1,200 r.p.m. and expanding to vacuum.

The reason for dividing a large capacity turbine into two or three elements running at different speeds is obvious. A certain quantity of steam has to be passed, which may increase in volume one hundred and fifty times, between inlet and exhaust, and drop five hundred degrees in temperature. This means beginning with very short blades on a small drum and ending with very long blades on a large drum. If these are all put on one spindle it is inevitable that considerable compromise must be made at the extreme ends, with a resultant loss in efficiency; and furthermore, the wide range of temperature in the same cylinder may cause troublesome distortions. With the use of two or more cylinders, the expansion is divided, making it unnecessary to resort to a compromise in blading distribution or velocities. The high temperature can be confined to one cylinder of smaller size and simpler construction, and not endanger the necessarily large size low-pressure sections. This may result in a more expensive construction, but is warranted by a greater efficiency and dependability.

Steam is supplied through a 24 inch main to the high-pressure turbine. It passes first through an automatic throttle valve, a steam strainer, and a governor controlled primary valve, and then enters the high-pressure cylinder from below. The steam chest, strainer, etc., are spring supported and are carefully aligned to remove the possibility of outside forces being exerted on the turbine cylinder, sufficient to cause distortions when the parts are expanding and contracting under load. Steam is exhausted from the opposite end of the high-pressure cylinder at about atmospheric pressure, when running at full load. The exhaust steam from the high-pressure cylinder passes into a cast iron overhead receiver pipe, which leads to the center of the low-pressure turbine where it divides, flowing either way into surface condensers below.

In connection with the marked increase in the capacity of steam turbines of late years, it is interesting to note that the size of the turbine has not increased in proportion to its capacity, owing to the development of the high-speed alternating-current generator; whereas the steam pipes have proportionately increased. This presents the problem of so arranging the header, that it will have a maximum flexibility at the point of contact with the turbine, and will not disturb the alignment or distort the cylinder by its expansion or contraction.

A 66 inch gate valve is located in the receiver pipe midway between the two turbines, for the purpose of isolating the one from the other in case of a shut down. Provision is made for the valve to be closed automatically in case either element should get into difficulty, and the necessity arise for its immediate removal from the line, without disturbing the other. This is accomplished by a specially equipped governor on the low-pressure turbine, which will be described later.

The turbine is designed to operate with 200 lbs. gauge steam pressure, 200 degrees superheat at the throttle, and an absolute pressure in the exhaust of one inch of mercury. The pressure in the receiver pipe is 12 lbs. absolute at 30,000 kw. The generators are each 23,600 kv.a., three-phase, 60 cycles, excitation being provided separately. A double condenser is provided containing 28,000 sq. ft. cooling surface in each shell and capable of maintaining a 29 inch vacuum with a load of 35,000 kw. and 60 degrees cooling water.

Flexibility in Operation.

This big unit is not radically different from the others of the same type. A distinctly new feature is the automatic device for cutting out either turbine if, for any reason, its immediate removal from service becomes necessary. By this means all the economic advantages of a 45,000 kw. machine are obtained with the flexibility of a 22,500 kw. that is, it is necessary to carry in reserve only 22,500 kw. rather than 45,000, as would be the case if it were a single cylinder or tandem machine. Each turbine and generator rotor is supported in its own bearings, so that four bearings are required for each element. They are heavy cast iron shells lined with babbitt and split horizontally, the upper half fitting into the lower, to prevent any side movement between the two halves. The bearings are self-aligned, being supported on spherical keys with sheet metal liners of definite thickness underneath, for horizontal or vertical adjustment. Oil for lubrication is

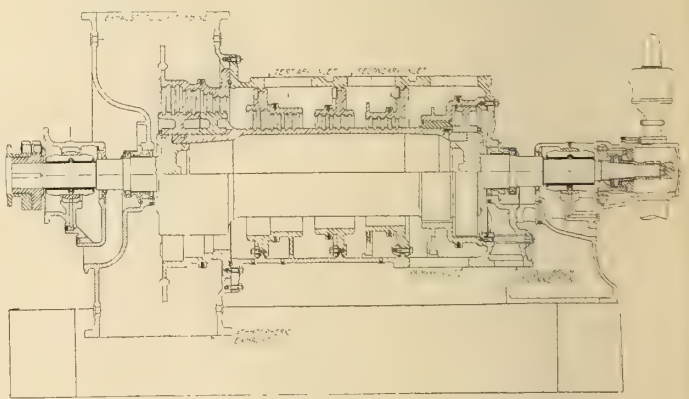


Fig. 1—Section through high-pressure single-flow turbine

admitted to the bearing casing at the bottom, is conducted through internal pipes to the top and distributed over the length of the journal through an oil groove. The sides of the bearing are eccentrically relieved for a space of about 35 degrees above and below the center line, to within an inch of each end, thus providing a reservoir of oil along each side. The journal is thus supported on an arc of about 110 degrees. It has a peripheral speed of 75 feet per second and a pressure of 110 lbs. per sq. in. on the projected area of the bearing.

Both turbines are equipped with Kingsbury thrust bearings capable of taking load in either direction, though when

running the thrust is toward the generator. Under normal operation they are loaded to about 300 lbs. per sq. in., but are capable of safely carrying twice as much. The peripheral speed is about 100 feet per second. These bearings are not only immersed in oil, but are supplied with a circulation of fresh oil through internal passages which deliver it nearer the shaft. The couplings are of the flexible pin type, providing sufficient flexibility to take care of any ordinary misalignment due to improper setting or to deflection of shafts.

The shafts are sealed with a water-gland which operates on the principle of a centrifugal pump, maintaining a water seal with a head greater than atmosphere, thus preventing air from leaking through the water filled chamber and into the exhaust. A steam seal is provided in an additional chamber along side the one in which the paddle wheel revolves, into which steam is admitted at a pressure of about five pound gauge, or a little above atmospheric pressure when starting up. This prevents air from leaking through the gland into the turbine while it is being brought up to speed or until the gland becomes operative. When running the steam is turned off.

The high-pressure turbine is of the single-flow reaction type. The entire cylinder or casing except the exhaust end is made of cast steel. The internal blade rings are separate and bolted in place.

High-pressure steam is admitted to the cylinder from below through the primary inlet, as shown in Fig. 1. It passes through the successive rows of blades and out through an overload exhaust to the low-pressure turbine. This particular turbine is arranged to carry 30,000 kw. on the primary valve with 175 lbs. steam and 100 degrees superheat at the throttle and 28.5 inches vacuum in the exhaust. For a load between 30,000 and 40,000 kw. steam is admitted through the secondary valve, thus by-passing the first five rows of four inch blades and entering the second stage which has five inch blades. This gives greater capacity but at a reduced efficiency. Similarly for loads above 40,000 kw. steam is admitted directly to the third stage, starting with six inch blades. The limit of capacity is approximately 50,000 kilowatts.

There are 24 moving and the same number of stationary rows of blades in the high-pressure turbine, beginning with four inch blades one inch wide on a 36 inch drum and ending with 10.5 inch blades 1.25 inch wide on a 50 inch drum.

The rotor is composed of three main parts, the body and two ends, besides which there are two blade rings on one end and two dummy rings on the other. The ends are pressed into the body on long taper fits and secured by tee-headed shrink links, making a thoroughly secure and rigid construction with a calculated deflection at the center of not over seven thousandths inch and a critical speed of 2,300 r.p.m. The normal speed being 1,800, there is left an ample margin to insure smooth running when properly balanced.

Low Pressure Turbine

The low-pressure turbine is of the double-flow type as shown in Fig. 2. Steam enters the center section and flows both ways, passing through eight rotating and eight stationary rows in each end, varying in length from six to eight inches, then passes into the exhaust chamber and down into the condensers below. As the load is divided equally between the high-pressure and low-pressure turbines at full load, the steam enters the low-pressure turbine at about atmospheric pressure.

The cylinder or stationary part is of cast iron and is composed of center and end sections, the blade rings being cut integral with the cylinder. The three sections are bolted and spigoted together and all are split horizontally. The upper three pieces are handled as one, the vertical joints never being disturbed after they have been once assembled.

The turbine rests on four supports applied directly below the horizontal joints, on each side of the exhaust chamber, and in line with the center of the exhaust opening. It is free to expand axially, sliding on these supports, with the turbine anchored to the inboard generator pedestal. A system of radial and axial stays in the exhaust chamber gives ample support for the spindle bearings and produces extreme rigidity in the whole structure, minimizing the possibility of distortions with change of load, or due to external pressure.

The low pressure rotor is composed of a central hollow drum rigidly secured to spindle ends on each of which is pressed two blades or discs carrying the low-pressure blades. The maximum mean velocity of the blades is only 515 feet per second which precludes the necessity of using other than a good grade of cast steel in the blade rings, as the rotative

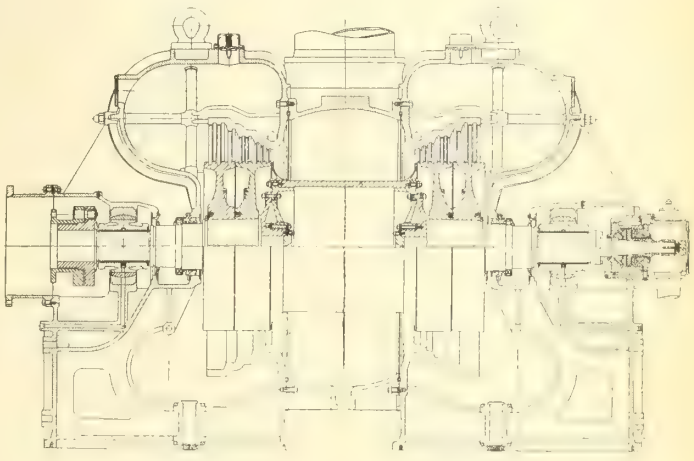

Fig. 2—Section through low-pressure double-flow turbine

stresses do not exceed 20,000 lbs. per square inch at 20 per cent. overspeed. This has a distinct advantage over a design containing special grade steels, which are not only hard to get, even in normal times, but in the use of which a certain hazard is always taken, through the possibility of an undetected flaw, or some part not being up to specification, and besides a little abuse in the way of improper heat treating on a highly stressed part may result in a costly failure. Owing to the double flow feature, ample blade area is provided to take full advantage of a high vacuum and still maintain a reasonable blade length in the last rows. Phosphor bronze blades are used, except in the last three rows of the spindle, which are drop forged steel.

Automatic Cut-out

One of the principal features of interest on this turbine is the means whereby, in case of necessity, either machine may be automatically or manually cut out of service without disturbing the other. Each turbine is provided with an overspeed stop governor which will shut off steam to that unit in case the speed should rise ten per cent. above normal. Each unit also has a speed control governor. The one on the high pressure turbine, which normally controls the steam supply to the whole system, is of the customary form. The governor on the low pressure element, while essentially the same, has some special features.

A gate valve is placed in the 66 inch receiver pipe, connecting the high and low-pressure cylinders, which is automatically closed by a hydraulic piston, under the control of the low-pressure governor, in case the low-pressure turbine should over-speed. The high-pressure turbine is provided with an emergency exhaust which will, in such an event, open to atmosphere through a relief valve, the turbine still continuing to carry load. Similarly if the two turbines are running together and the high pressure element should lose [illegible], steam will be shut off by its governor, when it will continue

with no load, or if it should over speed, the steam will be entirely shut off by the over speed governor. In either case, through lack of steam, the low-pressure turbine will slow down a certain percentage below normal speed, when the governor on the low pressure element will open the governor valve and admit live steam directly.

The governor on the high pressure turbine is adjusted for the usual close regulation of about three per cent. over the full range from no load to full load. The governor on the low-pressure turbine during this time must, of course, be inactive, neither admitting high-pressure steam through the steam chest, nor closing the valve of the receiver pipe. In this way, the travel of the low-pressure governor is divided into three zones:—the outer position, in which the gate valve admitting steam from the high is operated; the inner, in which is controlled the admission of high-pressure steam, when other source has failed; and the middle position, or neutral, where the high-pressure governor is controlling the system, and the low-pressure governor has no effect on the admission of steam, but is simply running idle.

It is desirable, of course, that the low-pressure governor should not be called upon to perform any of its functions, except in the case of an emergency, and in order that this position may be maintained properly by the switchboard operator, a system of signal lamps is arranged to show its position in the neutral zone. By changing the tension of the speed changer spring, the governor may be kept in its middle position, so that a normal fluctuation of frequency will not cause the governor to function. The spring on the low-pressure governor is designed to give a total speed range of twelve per cent. which is divided up as follows: Starting from the central position, if the speed rises four per cent. the governor is on the verge of tripping the low-pressure inlet valve. With a further rise of less than one per cent, the valve will be tripped shut, one more per cent, travel being provided

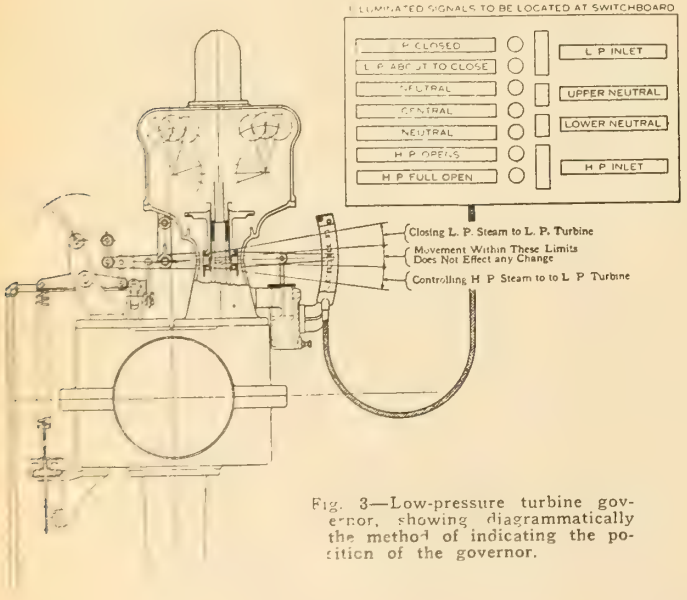

Fig. 3—Low-pressure turbine governor, showing diagrammatically the method of indicating the position of the governor.

for clearance. From the central position downward, should the speed decrease two per cent, the high-pressure valve will begin to open and will be full open after three per cent. more decrease. Another one per cent. is also provided at this end for over-travel.

The signal lamps in the switch board gallery, Fig. 3, are controlled from the low-pressure governor by a system of contacts operated by an extension on the governor level. As the governor moves between its inner and outer position this level travels across the contacts, registering its position on the illuminated sign.

Principal Features

To review the system briefly:—If the circuit breaker on the low-pressure element should open due to a short-curcuit, the turbine will speed up and close the steam inlet from the high-pressure cylinders. The high pressure turbine will continue to run, carrying its load and exhausting to atmosphere, while the low-pressure turbine, with its source of steam cut off, will fall in speed until reaching two per cent. below nor-

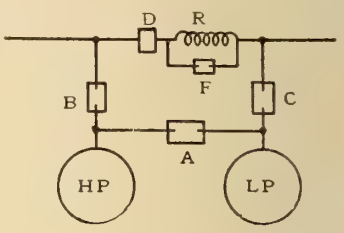

Fig. 4—Diagram of generator connections.

mal, when the governor valve will admit high-pressure steam. In the meantime, if the line has been cleared the unit may be synchronized and reconnected to the bus bars, the gate valve opened, and the low-pressure cylinder receive its steam as before. If the low-pressure turbine for similar reasons should overspeed ten per cent. and the automatic stop operate, it will result in the automatic closing of the high and low-pressure steam inlets, and the opening of the circuit breaker, and thus this half of the turbine will be entirely shut down. The high-pressure element, however, will continue to run non-condensing and carrying its load as usual.

If the circuit breaker on the high-pressure turbine should open and the load be dropped, the supply of steam to the system would diminish, and the speed would fall until the low-pressure governor valve opened, admitting high-pressure steam to carry load. The connection from the high to the low-pressure cylinder would remain open, the no-load steam on the high-pressure element continuing to help run the low. After the electric difficulties have been removed the high-pressure generator can be synchronized and placed back on the line and the load carried as before.

If the high-pressure turbine should overspeed ten per cent. through some local cause, and the automatic stop operate, the main throttle and governor valve would close, shutting off all steam to the system. The circuit breaker would open and the machine shut down. The speed of the low-pressure element would immediately drop until its governor valve opened to admit high-pressure steam to carry the load. In this case the steam seal on the high-pressure glands should at once be turned on to prevent an air leak into the system unless, however, the inlet pressure is kept above atmosphere. In case it is necessary to run the low-pressure turbine alone for any length of time, the gate valve in the receiver pipe should be closed.

Attached to each throttle valve and operated by it is a switch whose function is to operate the main circuit breaker. The throttle valve is tipped out by the emergency stop and in this way not only is the turbine absolutely isolated, but the generator also. The operation of the throttle valve by hand, however, does not operate this switch.

The low-pressure element, is served by two 28,000 sq. ft. surface condensers or a total area of 56,000 sq. ft. The condensers are spring supported, there being no expansion joints between the low-pressure turbine and condensers. They depart from the standard construction in that the circulating system of each condenser is divided into two parts, so that one half can be in operation, while the tubes in the other are being cleaned. Each condenser is equipped with two water

inlets and outlets, and also has two air off-takes, one on each side of the condenser shell. The condenser is supplied with 74,000 gallons of cooling water per minute, by three circulating pumps of the double impeller type. All the circulating pumps are turbine-gear driven. The air removal apparatus consists of two sets of Westinghouse-LeBlanc wet air pumps, each of which is capable of completely removing the air, so long as the leakage is normal.

The water supply for the air pumps is taken from a steel tank. Both sets of pumps discharge into one tank, and the air pump water is used over and over again. Of course this arrangement requires a certain amount of make-up water to keep the temperature of the air pump water down to normal. This is taken from the service line. The overflow from the air pump tank is ordinarily discharged into a sump. Due to the fluctuating water conditions at Brunots Island Station, booster pumps were also supplied in order to take care of the overflow during periods of high water in the river. The condensate is removed by means of centrifugal pumps, each of which is capable of handling the maximum condensate. The air and condensate pumps are driven by the same turbine, but are not on the same shaft, there being a coupling between the air and condensate pumps.

The two three-phase, 60 cycle, 12,000 volt generators are designed for the same output at full load. The one connected to the high-pressure turbine has four poles and runs at 1,800 r.p.m., while the one connected to the low-pressure turbine has six poles and runs at 1,200 r.p.m. In spite of this considerable diameter in speed the D^2L as measured at the outside diameter of the punchings, as well as the length of the core, is almost the same in both cases, it being but 3.5 per cent. higher in the low-speed generator. On the other hand, the D^2L measured on the active diameter and length of the rotor is 45 per cent. higher in the low-speed machine. The reason for the D^2L being nearly the same at the outside diameter is due to the fact that the high-speed machine has a considerably greater depth of punching back of the slots, because of the larger flux per pole per inch of length axially.

Each generator requires approximately 70,000 cu. ft. of air per minute for cooling. With this large volume of air, the air temperature rise, and the iron temperature rise are both comparatively low. The air is supplied from separate blowers, and the two machines require approximately the same pressure to circulate the needed air through them, this pressure being about 4.25 in. of water. All the air is washed before it enters the generators, thus insuring against clogging of air ducts and tending to decrease danger of burnout. Air to the amount of one and one-third times the weight of the generators passes through them per hour. Also approximately 1.4 times the weight of steam needed to drive the generators with full load of 40,000 kw., is required in air for cooling.

The stator insulation in the buried portion in both machines is mostly mica, and is capable of withstanding continuous temperatures of 150 degrees C. The rotor insulation in both machines also is mostly of mica, and is capable of withstanding the same temperatures as the stator. The stator coils of both machines have but one turn each, there being parts of two coils in each slot. That only one turn per coil is needed with 12,000 volts is due to the fact that the generators are so large, and a small number of turns in series is required to generate the total voltage. With one turn per coil, there is no danger of break-down between turns, which is an important item with over 200 volts per turn, and a breakdown between turns wouuld mean not only the destruction of the insulation, but would also probably be accompanied by great damage to the core. In order to reduce the eddy current loss in the stator coils to a point where the temperature will not become dangerous, the coil is well stranded, and the strands are transposed from one coil to the next, thus bringing the top set of strands of the first coil in series with the second set of strands of the second coil, the third set of strands of the third coil, etc.

In order to protect the generators in case of fire, arrangements have been made to inject steam into the air intake just below the entrance to the end bells and, in addition, there is provision for shutting off the air as soon as fire is discovered. This means has been found to be quite effective.

The generator fields were designed to have approximately the same exciting voltage at full load as that required by the other generators previously installed in this station, and with which this unit is to operate in parallel. This enables fairly efficient operation, as very little external resistance is needed in series with the field windings of the generators when an automatic regulator is used. It also permits the use of a common storage battery for emergency excitation of this and the other units.

The scheme whereby the two generators are paralleled is given in Fig. 4, in which A is a switch which is manually operated and is used only to connect the two generator windings together when the unit is started. When starting, with this switch closed, the fields of the two generators are excited so that the two units are kept in step from a standstill. When the machines are up to speed, the switch A is opened. D is a nonautomatic circuit breaker, R is a reactance, and F is a circuit breaker which opens in case there is a short-circuit on either side of the line. In case of a short-circuit the reactance R prevents a prohibitively high current from flowing from the second machine to the point of breakdown. B. and C are differential automatic protective devices for the two generators.

Accident Under Peculiar Circumstances

A rather unusual case is just now being tried before Justice Middleton in the non-jury assizes. The plaintiff, a woman, is suing the Toronto Street Railway Company and the city of Toronto for $5,000. It appears that she alighted from a street car at one of the intersections and in order to avoid a pool of water and a waggon belonging to the city she crossed the road and was struck by a car turning the corner in the opposite direction. The plaintiff contends that the street car should not have stopped at a point where passengers could not be discharged with safety and that the city should not have allowed the pool of water or its team to remain on the street at a point where passengers alight. The city contends that it was under no obligation to remove the water, that the team was being used in a reasonable manner and that the accident was due to the plaintiff's negligence. The railway company also denies liability.

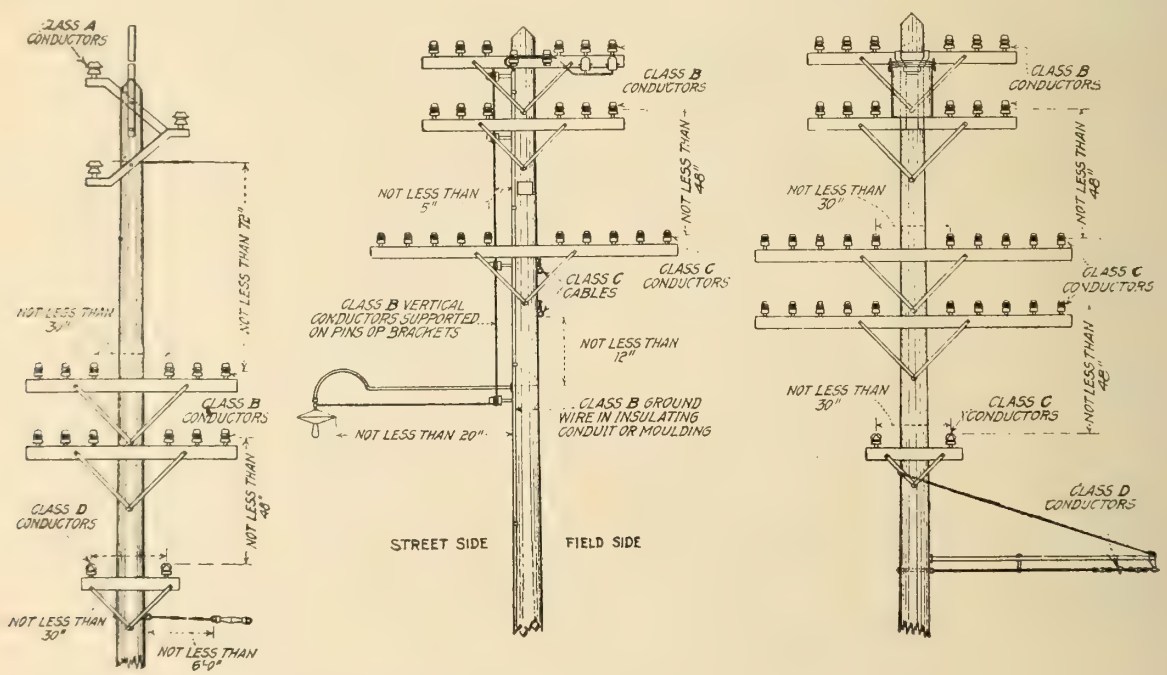
Re-Construction Work in Sherbrooke

There were two typographical errors in the article on Hydro-electric Reconstruction at Sherbrooke, published in our issue of November 15. On page 31 it was stated that the Frontenac street power house plant consisted of two water wheel generators of 25 kv.a. each. This should have read '625 kv.a. each." On page 32 reference is made to the Rock Forest Transmission line and the three Canadian Westinghouse transformers are described as of 533 kv.a., 6600-2200 volts. This should have read "633 kv.a., 6600-2200 volts."

The fare on the Boston Elevated Road has been increased to 8 cents. In August last it was raised from 5 to 7 cents. School children will be able to purchase tickets at the rate of 5 cents each.

Joint Usage of Poles—a Workable Economy

By T. N. Bradshaw*



Two or more lines of poles erected on the same side of the street or highway are not only unsightly but represent an economic loss and a waste of timber. Where the wires on such conflicting lines are carried at or near the same level a serious electrical hazard to persons or property is liable to be created owing to the proximity of the wires of different classes and the liability of contact between them or the possibility of employees working on one class of wires coming in contact with another.

The most practical way of eliminating the losses and hazards referred to in connection with lines located on the same side of the street appears to be a properly constructed joint-use line having a well-defined space for the wires and fixtures of each occupant. These spaces should be separated from one another by an ample vertical clearance space. They should also be provided with a suitable climbing space so that employees of the various companies using the poles can ascend and descend them without coming in contact with the wires through which they may have to pass.

A wide experience covering a number of years with lines constructed as outlined above seems to indicate that the clearance space should be not less than 40 inches vertically between signal wires and attachments and electric light or trolley-feed wires and attachments. Experience also shows that a climbing space of not less than 30 inches wide on either the back or field side of the pole is necessary in order to provide for climbing and for the raising and lowering of transformers. It is, of course, preferable to provide a greater vertical separation than 40 inches between signal wires and wires carrying high voltages, and many companies endeavor to have this space not less than 6 ft., particularly with new lines, using the minimum clearance of 40 inches only on old lines that are made joint after the line has been in service for some length of time.

The street side of the poles should always be reserved for the vertical runs of the electric light or power wires, and the field side for the vertical runs of signal wires. Owing to the fact that there is no known protective device that can be placed on a signal circuit that will afford adequate protection against the potentials carried on high-tension circuits, it is not considered advisable to place telephone, fire-alarm or other signal circuits on the same poles with such circuits. High-tension lines should, wherever practicable, be constructed on rights-of-way remote from those occupied by the signal lines. (By high-tension circuits are meant the following: Constant-potential, alternating-current, neither side grounded, exceeding 5000 volts; constant-potential, alternating-current, one side or neutral grounded, exceeding 2900 volts to ground; constant-current, series-metallic, line current exceeding 7.5 amp., and constant-potential, direct-current circuits including feeders and trolley-contact wires, one side grounded, exceeding 750 volts to ground).

Pole lines located on the opposite side of a street or highway are not considered as conflicting, but the same precaution should be observed, when erecting separate lines of poles, regarding the relative levels of the wires of different classes. That is, electric light or power wires should be carried on a taller pole line. This will enable electric light service wires crossing the streets to be carried over the telephone wires, and telephone wires from the opposite side of the street to be carried under the electric light wires. This practice prevents the interlacing of the service wires, which is liable to be a serious problem in congested streets.

Relative positions of power, signal and trolley wires on joint poles.

In order to bring about the conditions outlined in the foregoing it is necessary to have some form of inter-company agreement covering not only specifications and methods of construction and the reservation of space requirements, but also a fair division of the construction and maintenance costs. In Connecticut the matter is helped along by fair-minded legislation, and the Public Utilities Commission of Connecticut has promulgated in its Order "D" docket, No. 1447, a set of rules and specifications under which most of the wire-using companies of the state have been operating for some time with very satisfactory results.

Since most of the lines in Connecticut have been placed

*Chairman of Committee on Joint Usage Rules, before International ...ciation of Municipal Electricians.

on a joint-use basis and the construction standardized there has been a marked decrease in the number of fatal accidents to the employees. This is undoubtedly due to the fact that employees working on signal circuits no longer have to climb through electric light wires in order to get at their own work, and the electric light wires are generally placed so far above the signal wires that electric light employees are not apt to come in contact with grounded conductors of another class while working on high-voltage wires.

There is another feature which appears to make joint use preferable, particularly in cities and towns where there is considerable local distribution; that is, that the city or town is more completely covered by the pole lines of the two companies, and many companies have reasoned that it is better to own one-half of all the poles in a locality rather than to own all of one-half the poles.

In order to insure the success of any joint-line arrangement, particularly where electric light and signal lines are to occupy the same poles, the broadest possible co-operation must be indulged in between the various occupants for eliminating inductive interference. Electric light lines should always be kept free from grounds that might upset the electrostatic balance to ground, also long single-phase taps from three-phase circuits should be avoided wherever practicable. The voltage wave developed by the generators should be as free as possible from noise-producing harmonics, and consideration should be given this fact before the generating machinery is purchased from the manufacturer. Deviation from the pure sine wave should not be allowed to exceed the limit set by the American Institute of Electrical Engineers. These precautions are quite necessary in connection with electric light or power circuits, because it is not always possible to transpose telephone lines, for instance, so as to eliminate all inductive interference. In many instances it has been found necessary to place transpositions in the electric light or power circuits to co-ordinate with those in the telephone circuits.

In Connecticut alone there are approximately 1,700 miles (2 700 km.) of pole lines used jointly by electric light and telephone or other signal lines. Practically all of this joint line mileage is standard as regards location of the wires and vertical or lateral separation, so that it is fair to say that the joint-use line is, under proper regulation, a success, simplifies the distribution problem and works toward safety.

While it is sometimes more expensive to erect a joint line, the cost to each occupant is usually less than a separate line or poles would be. The maintenance costs are also less because of this division of the charges. The lines appear to stand up better under the influence of severe storms because of the fact that such joint-use networks are usually much better guyed or braced than a single line would be. Moreover, such lines receive more attention from the engineers in order to make them satisfactory to all parties concerned.

Is the Zone System the Fare Solution?

By Thos. Conway, Jr.*

The electric railway industry stands face to face with the greatest crisis in its history, not even excepting the revolution which followed the electrification of the horse-car lines. The problems of the early 90's were technical and concerned the handling of a largely augmented business by a new and untried method of propulsion. The problems of to-day are financial and concern the method of saving an industry whose entire economic basis has been undermined.

In the early days of the war, when the prevailing opinion was that the struggle would be comparatively short-lived, the remedy for the electric railway situation seemed to be a temporary increase in fares which would carry the industry over the crisis. With slight advances in labor costs and the practical certainty of a marked reduction after the war in the prices of materials, it then seeemd possible to return speedily to substantially a pre-war basis. It was this situation which caused electric railway operators to move for a horizontal increase in fares to 6 cents, resulting in an increase in revenue of about ten per cent., sufficient to offset the then increased cost of operation. The 6-cent fare was easily understood by the public, and its adoption would destroy the popular belief that a nickel and a street car ride were synonoymous. Everyone felt that after the war was over it would be possible to fix the rate of fare with reference to the cost of service.

It is apparent that there is now no likelihood of a return to pre-war operating costs. The war hastened the process of readjustment to a higher cost level, which would have occurred over a period of years in any event.. Labor, which represents 60 per cent or more of the cost of operation of the average electric railway, has secured very large increases which must in the nature of things be more or less permanent. The solution, whatever it may be, should therefore not only carry the industry through the war, but furnish a sound economic basis for a period of years.

Turning to the Zone System

Up to the present time two alternatives have been seriously considered. The first involves a horizontal increase in the unit of fare to 7 cents or more, as the case may require. The experience thus far secured is fragmentary, but it is apparent that progressive reductions in travel. If a 6-cent fare increases revenue 10 per cent, a 7-cent fare will not increase revenue 20 per cent. Indeed a point is soon reached where a further increase in fare will bring about an actual decrease in revenue. Just where this point is will vary with each particular property, but it is safe to say that the practical limit of horizontal rate increases has been reached upon many properties.

It is this situation which has caused the thoughts of a large percentage of the industry to turn to some sort of a zone system as a possible solution. In substance, the fundamental idea of a zone system is that the rate of fare shall bear some relation to the length of ride. The application of this principle takes various forms. In Europe the passenger fare varies directly with the mileage traveled. In this country the practice has heretofore been to establish certain arbitrary zones. A person traveling in a zone pays a certain rate, and his fare increases with the number of zones through which he travels.

Manifest Advantages of Zone System

The appeal of a zone system is due to its manifest advantages. While higher horizontal rates inevitably cause a reduction in the volume of a utility's business, a properly devised zone system would hold a larger proportion of the existing travel. A 6, 7, or 8 cent fare discourages short-distance riding, which under proper operating conditions constitutes profitable business.

From the standpoint of the public the zone system has

*Professor of Finance, University of Pennsylvania, before American Electric Railway Association

the great advantage of making the long rider pay a correspondingly higher fare than he who takes a short journey. The system appeals to the public, because a man pays for what he gets. It is true that the plan appears to saddle all of the extra costs upon a portion of the public rather than distribute the burden equally over the company's entire business. As long as the public regards increased costs as a temporary condition this argument has weight, but when it is understood that the increase will be in a large measure permanent, this contention loses force.

No Present American Zone System is Entirely Satisfactory

It has been my privilege to visit recently every city in the United States in which a zone system exists, to talk with the operating officials and to study the actual operation of each system. Judging from the standpoint of the financial results secured, I believe it can be said that no zone system now in force is entirely satisfactory. The Milwaukee zone system (in force upon the suburban lines alone) produced the revenue predicted at the time the original plan was formulated—a sum insufficient to meet present costs. In every other case the revenue producing possibilities of the system have been greatly over-estimated. In one of the most important of the recent experiments, the over-estimate amounted to as much as 40 per cent of the estimated operating revenue.

More Speedy and Safer Fare Collection Needed

The great difficulty with zone systems, as thus far employed, concerns the collection of fares. In general, two methods are employed. In either case city fares are collected in the ordinary manner, registration being effected with a fare box, overhead register or some other of the many fare collection devices now generally employed. In some cases, the fares on suburban lines are similarly collected and registered, the conductor going through the car and collecting the fares at each zone limit. Where outlying zones of one or two miles are used and the schedule is rapid, the conductor spends his entire time in successive trips through the car collecting fares. The practice is annoying to passengers and keeps the conductor off the rear platform, thereby increasing boarding and alighting accidents.

The alternative to this method is the even more cumbersome plan of using a duplex ticket. This method is employed on a number of systems, the plan being to collect the entire suburban fare as the car passes the limit of the central 5 or 6-cent area. Over-riding can be guarded against only through the use of hat checks, periodic inspections of the portion of the duplex given to the passenger or surrender of the duplex ticket as the passenger leaves the car. This method is so cumbersome that it is only practicable where there is no considerable amount of boarding and alighting at frequent intervals. It has proved impractical in city areas.

Its greatest defect concerns the possibilities of stealing on the part of conductors. Some idea of the extent of such losses can be secured from the experience of one of the most important companies which have tried a zone system. The news of the arrest of a number of conductors was followed by an increase of 10 per cent in passenger revenues, beginning on the succeeding day. No amount of inspection, however, appears to prevent the misappropriation of fares where travel is heavy and haste in collection is necessary.

The application of such collection methods to lines located wholly or in large part in the thickly built-up city territory is impossible. The Rhode Island Company and the Bay State Street Railway have recently decided to go from a system where rates of 2, 3, 5 or 6 cents per zone prevailed to a basis of either 5 or 10 cents per zone. A system with 5-cent zones is no different from that which has prevailed for many years in this country.

The only other method of fare collection thus far tried under strictly urban conditions is the plan employed in Pittsburgh. As the Pittsburgh Railways has pointed out, this is not a zone system but two flat-rate systems, one superimposed upon the other. The fare within a prescribed area, including the centre of the city, is 5 cents. Anyone travelling from the centre of the city to a point beyond the limits of this central area pays 7 cents, while the same rate of fare is charged for travel between any two points situated within this outside ring. From the standpoint of fare collections this system is simple. It, however, has the same disadvantages inherent in the high unit fare, because it discourages short riding in the outer zone in which a large proportion of the population is situated.

Better Method of Fare Collection.

After careful study, I am convinced that the successful application of a zone system in thickly built-up city areas is predicated upon the development of a more speedy and safer method of fare collection. The successful system of fare collection must be one in which the opportunity for the passenger to beat the conductor or for the conductor to misappropriate the fare is reduced to a minimum. Where fares of varying units are collected, it is out of the question to register them serially upon one register, even though a fare box or some other pre-payment device is employed.

One of the most prominent electric railway operators recently said to me that the industry would be saved if the men in it had brains enough to work out their own salvation. His conclusion is certainly true concerning the zone system. The problem of the moment, in so far as the zone system is concerned, is to devise a method of collection which will meet the practical conditions prevailing in all of our large cities. If a practical method of collection can be devised the zone system, in my opinion, furnishes the solution for companies whose average ride exceeds a mile in length. The possibilities of a zone system are now the subject of serious study and investigation by some of the largest companies in the country, and it is to be hoped that the solution will be shortly hit upon.

A zone system should encourage short riding. The long rider should be made to pay an adequate fare for the journey which he takes, and the cost of furnishing the service which he uses. Business should be encouraged rather than discouraged. The automobile, the improved highway and the jitney have taken enough of the business of the electric railway. More travel rather than less should be the goal.

Even with a satisfactory system of fare collection at hand I doubt whether it would be possible to work out a zone system of fares which would meet the financial necessities of many properties. I have recently seen a number of properties whose future seems hopeless. Sufficient travel can not be secured at rates of fare which will produce adequate revenues to defray the present high cost of operation. Indeed the extremity of the electric railroad industry is so great that every opportunity should be seized upon to convince the public that the function of the railway is to provide transportation rather than serve as a medium of reducing general tax bills.

Taxes at Expense of Public

In the days when the 5-cent fare ruled supreme, municipalities and states alike levied taxes and burdens of one kind or another upon the electric railway, upon the theory that whatever they got was at the expense of the utility owners rather than the car rider. To-day increased expenses must be immediately reflected in increased fares. There is no reason why the average car rider should pay higher

fares in order that streets be maintained for those who own motor trucks and pleasure automobiles. Franchise taxes levied upon the gross receipts of companies, payments for snow removal, street sprinkling and the like, will from this time forth require percetpible additions to the rate of fare.

It should be pointed out to the riding public that they are the ones who pay electric railway taxes, through higher fares. This is true whether a company operates under a sliding-scale fare, the "service at cost law" in Massachusetts or the strict control of a public utility commission as in most of our states. The utility's profits are in all cases limited to the amount necessary to induce capital to enter the business. When earnings exceed this amount rates are reduced, and when they fall below this requirement, rates should be immediately increased.

It is gradually beginning to dawn upon the people of this country that the days of profiteering in electric railways ended some years ago, and that if the electric railway is to survive it must be helped rather than hindered, and must be allowed to charge a rate of fare which it sufficient to maintain its solvency and to permit it to continue to serve the public. That the cost of the service, by whomsoever provided, must be met, goes without saying. The next few months will be the most critical in the history of the industry. Its entire future hangs in the balance. It can not long continue upon the present unsound economic basis.

Why the Railways Need Higher Fares*

I shall not attempt to review the events of the past year as they have affected this industry, nor shall I try to point a way out of the alarming situation in which we find ourselves. That is the province of this conference.

I do desire, however, to emphasize a point which I believe has not been so forcibly impressed upon the public from whom we are asking increased revenue as it might have been.

The leading economists of the country unite in the statement that the purchasing power of the dollar has declined at least 50 per cent. since the early nineties. In other words, the 50 cents of that period bought what it requires $1 for to-day. And this means to the street railways of the United States that the 5-cent fare of the nineties is now less than a 2½-cent fare.

In our request for a higher fare we are, therefore, asking nothing more than that what we receive for the service rendered shall be restored to somewhere near its real worth at the time when the rate of fare was fixed. The coin dropped in our fare boxes to-day bears as an impress "5 cents"; but as compared to the 5 cents which was stipulated in our franchises or fixed by statute as our lawful and legal fare, it is 2½ cents and no more. To put the street railway fare upon a parity with what was received in the decade 1890-1900, under a franchise, a statute, or an agreement, calling for the nickel unit, it would now be necessary to substitute the dime for the nickel.

The wages paid to the motorman in this earlier period were approximately 20 cents an hour. With a single fare we could therefore pay for fifteen minutes of his time. To-day, through the action of the federal government, the motorman's pay approximates 38 to 48 cents an hour, and a single fare pays for but eight or six minutes of his time according to the rate of wages, and this in varyingly increasing ration is true of all that we must use to render our service.

On the other hand, taking $2 a day as the average wage in the earlier period, the workman using the street car to ride to and from his work was compelled to pay out 5 per cent of his day's wages for transportation. To-day, with an average wage of $4, and this is probably much less than the correct figure, he pays for the same purpose but 2½ per cent.

This decreased purchasing power of the dollar is not a product of the war alone. The war but gave it an additional, although a mighty, impetus. It has been a gradual development and in other industries it has been accompanied by an increase in price of commodity, which has at least kept pace with and, in some cases, passed it.

It has been in part overcome in the electric railway field by extraordinary improvements in apparatus and methods, the result of millions spent in experiments due to the enterprise and initiative of railway men and manufacturers of which the public reaped the benefit.

The limit of economy made possible by these improvements in operation was, however, largely reached some time before the war, and for a number of years the difference between the cost of producing our service and the price at which it was sold has come from the pockets of those whose money is invested in the industry.

That was the situation when the war sent the price of everything which we must use in producing our product soaring skyward and left the price at which we sell stationary.

It is plainly evident that whether the public shall decide to operate the street railways, whether it assumes greater control over them, or whether it allows them to remain in the hands of private investors, that the unit of their fares, the price at which their product is sold, must be restored at least to the level which prevailed in past years.

I have confidence in the common sense and judgment of the public. I believe that it stands ready to pay a fair price for what it receives and I conceive it to be our main duty both as members of this association and as operators of electric railways to see that the public is informed as to what such a fair price really is, not in terms of coinage, but in those of value—that is purchasing power.

*From the address of President L. J. Stanley, before the recent New York Conference of the A.E.R.A.

New Book

The Decimal System—by Charles Hoare; Effingham Wilson, 54 Threadneedle Street, London, Eng., publishers; price one shilling. This book, which contains 85 pages, has been compiled with a view to the daily requirements of the artizan and mechanic rather than for the man with scientific training. It is intended that, with moderate practice and study, it should be possible for any one acquainted with the simple rules of arithmetic to obtain with ease and accuracy the result of calculations connected with their daily occupations and which they have hitherto been accustomed to consider as wholly beyond their reach. The author has borne in mind that the elementary principles of decimal arithmetic are practically unknown to a large number of workers and that by acquiring this knowledge in compact and understandable form they will be of much greater value to themselves and their employers.

Passenger traffic on the Toronto civic car lines for November shows increases of 219,974 in the number of persons carried and $3,233 in revenue over the same month last year.

A newspaper report states that the Italian Minister of Finance proposes, among other things, state control of the sale of electric lamps.

The Dealer and Contractor

The Next Ten Years will see the Average Farmer with an Electric Plant—Who Gets the Business, the Machine and Automobile Agent or the Electrical Contractor-dealer?

We have made a very thorough investigation of the prospective field for electric light and power plants for the farm home. We are now confident that within the next ten or twelve years at the most, it will be extremely difficult to find any farm home, except those occupied by renters, which will not be equipped with an electric light and power plant of some kind.

I am convinced that the farm-lighting plant market is going to develop much faster than did the automobile market. The reason for this is apparent. Ten or twelve years ago, when the automobile manufacturer first began to build up a dealer's organization in small rural trading centers through which to develop the farm market for automobiles, there were at that time probably not more than one or two farmers out of each ten who had available cash. Furthermore, at that time, the farmer had to be convinced that the gasoline machine was a practical machine for him. Up to that time, he had not come into close contact with the improved living conditions in the cities where the inhabitants had access to all the comforts and conveniences which belong to the city home.

To-day there is probably not one farmer out of ten, excepting renters, who cannot afford to invest $600 or $700 for a complete electric light and power plant and its equipment for his home.

The automobile has largely done the missionary work for the farm-lighting plant. The automobile has educated and thoroughly convinced the farmer that the gasoline engine is a practical equipment for him. Almost every farmer owns an automobile, a great many of them a truck or tractor or probably one or more stationary engines for grinding feed, sawing wood, pumping water, churning, washing and other purposes. Many other educational influences have recently been at work for the farmer.

No doubt when you hear that $30,000,000 worth of electrical equipment was sold the farmers last year and $60,000,000 this year, you probably wonder who has sold them this equipment. I can assure you it is not the mail order houses, for electrical equipment is entirely too mysterious a proposition for a farmer to buy from a mail order house. Some little of it has been sold by the farm implement dealer, but very little, as he knows little about it and as a rule lacks the necessary sales ability to sell the farmer lighting plants.

Who Should Sell Farm-Lighting Plants?

Who is the logical man to sell farm-lighting plants? I will let electrical dealers answer this for themselves when they have reviewed the facts. Isn't it true that farmers of to-day know more about gasoline engines than any other class of merchants, not excluding even the automobile salesman? It will not take him long to find out and tell you whether or not your gas engine is right. Who besides the electrical dealer is sufficiently versed in electricity to know whether the electrical equipment is right for the farmer's needs? Who knows what the farmer can or cannot do with the plant or what he should do or should not do? Which is more important: To sell the farmer a very fine light plant and set it in his basement and run a few lights around so that he had to get up on a chair to turn them on and off, or to put in a light and a switch where he needs it and can reach it conveniently? Who can wire it with the proper size of wire so the farmer will not have a continual loss? Who understands how to wire for his washing machine, cream separator, pumps, vacuum cleaner and heater plugs so that he will not burn the contacts off his iron while pulling out the plug? Who can wire all his outbuildings so he can have lights when and where he needs

Farmer is Concerned with Results.

We have found in the installations we have made that the farmer knows and cares very little about the plants that make the light. The result is what he desires. Farmers tell us how fine it is to work in a nicely-lighted barn and outbuildings and how the big light out in the yard lights up the neighborhood, and how he turns on his cream separator and goes in and eats his supper. Then Mrs Farmer tells us the motor has taken all the work out of washing and she would not be without the electric iron for the price of the plant, and "those two lights on my dresser are the finest things. I never really saw myself in the glass at night until I got those. In fact, we are just so pleased with everything except that $15 fixture in the living room. It don't look good enough beside the two $50 fixtures in the parlor and dining room, and as we got off so much cheaper than we thought we would, Mr. So and So says I can have this changed." Mr. So and So speaks up and says, "Yes, we have lived on this one farm for fifty-five years, and the $1,050 we spent with you is the best improvement we ever put on the farm and there isn't money enough in your city to buy this back if we could not get another."

This customer is simply a good, substantial, progressive farmer who has worked and worked hard for all he has and spends his money wisely. His is only one example of all our installations, which we insist on being as complete as his. When these farmers express the great pleasure they get from the light, we attribute very little of it to the plant in the basement. However, we do insist on the plant being one we consider the best. But the farmer's great satisfaction, we think, comes from the complete and conveniently designed installation which we insist each must have. We surely think the barber, the plumber, or hardware man is going to have some job putting across one of his cheap installations in the vicinity of one of our plants.

The reason the electrical contractor and dealer has not sold these plants in the past is that he has failed to introduce

From a paper presented before the Illinois State Association of Electrical Contractors and Dealers.

salesmanship into his business. How many times he has sent to his prospective customer a price on something and closed the accompanying letters by saying, "I sincerely hope our price will be low so you can give us the business." If we had all the paper we wasted this way, it would be worth a lot of money now.

It always seemed to me that an electrical engineer felt that it would be below his dignity to try and sell his product like other merchants, although he is a merchant like anyone else. A few years ago, however, we accidently got hold of an engineer that must have beeen born a salesman, for he certainly didn't learn it around our office. He would not mail his proposals, but he would take them out and stay with the prospect till he came back with the job at the highest figure submitted. Then after he got the job, everything had to be done just right. He was a hard man for our men to work for at first, but he soon convinced them it was no harder to do things right than to do them otherwise. This man soon developed a clientele that did not care to go to the trouble of getting bids. They would simply leave it to him. He is now helping design the electrical equipment for the new boats of the United States Navy. Before he left he gave us a taste of what salesmanship would do for our business, and we have endeavored to progress on these lines, slowly but surely, since.

I am very sure the electrical contractor-dealer is the logical man to develop this farm-lighting market. But he must wake up if he would get the business and prevent automobile dealers from selling half-made jobs to the farmer. My advice to the electrical contractor-dealer is to get into the farm-lighting business at once. It is a good war-time business and will be a better business after the war. Moreover, it will enlarge the field of the contractor-dealer. Your sales organization can be utilized for city sales at such times as they cannot get out into the country.

While our firm was not a pioneer in this business and we do not know that we have gone at the thing just right, I am willing to tell something of our experience. We first had a meeting and talked over the proposition of selling farm-lighting plants. It was a pretty cold meeting. There wasn't very much enthusiasm over it. About the only one in favor of it was myself, and as I couldn't see any other business in sight with a spy glass, and as I was general manager, I was able to put it over.

Finding the Plant and the Prospects.

We then started to choose a plant to sell. We considered the merits and demerits of them all and finally picked on one we thought was the best. We ordered one of these on a three months' trial, and gave it a thorough practical test. After this test we became thoroughly sold on this machine. It may be possible that the manufacturer of this plant had better salesmen than the others, but as we in our own minds feel that we are selling the best, we believe that is all that is necessary.

We next fitted up a demonstration room in our basement. It was done in mahogany woodwork and furniture. It had rugs on the floor and was just as nice a room as you would see anywhere. We installed the plant in running order, connected up the batteries, hung fixtures, connected up an automatic water system, electric washing machine, vacuum cleaner, toaster, iron and cream separator. In fact, we have every device there that can be bought for 32-volt circuits.

We then got a Prairie Farmers' directory giving names of all the farmers in our territory. These were card indexed. All the farm owners, large tenants and other prospects were placed in a mailing file. We mailed a personal letter explaining our entrance into this field. We followed this up in a week by a circular of the plant with a return postcard. We received two cards back out of 3,500. This convinced us the farmer will not admit to anyone that he wants to buy anything. He is afraid you might sell him. We followed this with a catalogue of the plant. This we followed with a descriptive flyer of the plant and different accessories he could use with the plant and cuts of a few lighting fixtures.

By this time we had a plant installed. We photographed the farmer's home, got a testimonial from him and had this all printed on a flyer with a little selling talk and mailed these to each of our list. We get out one of these flyers each month.

How Many Trips It Takes To Sell a Farmer.

In the meantime, we had started out our salesmen to call on the farmers, to get acquainted with them, to learn to talk about the crops. In this we learned to always bear in mind that you can't sell a farmer the first trip, seldom on the second trip, rarely on the third, sometimes on the fourth, maybe on the fifth, possibly on the sixth, more probably on the seventh, but more likely on the eighth. Still your chances for making the sale are better on the ninth trip, but the tenth seems to be the good average number.

The hardest proposition of all is to get a salesman that can sell a farmer. A good city salesman rarely has the patience to sell the farmer. To sell the farmer, a salesman must first of all know his product through and through. He must be absolutely honest. While an untruthful salesman will not get very far any place, he absolutely cannot sell the farmer a lighting plant. To make a sale of a plant to the farmer, the salesman must get his confidence, must keep it after the sale while the wiremen are making the installation. Even after the job is completed it is good practice to have the service man call on the farmer once a month and see how things are going. Show him that you are still interested in his plant after you have his money.

We have found that such service men are less expensive to have than salesmen. If the service men's work is well done, the farmer, who is your customer, will do your selling for you in his neighborhood.

Toronto Illuminating Engineers Meet

The monthly meeting of Toronto illuminating engineers was held in the MacLean Building at 347 Adelaide St., West, on Friday, Dec. 3. Lieut. Oliver gave an address on artificial daylight, and explained the properties of a special form of daylight glass, his own invention, outlining the legion uses to which such glassware is being put. A number of curves, prepared by Lieut. Oliver, showed that the spectral intensity through the special glass demonstrated, coincided very closely with that of northern daylight, being somewhat low at the violet end and high at the red end of the spectrum. This, however, the speaker explained, was for sentimental reasons, the excess of red appealing more strongly to the average customer. If required, the process of manufacturing could easily be varied to duplicate, exactly, the natural daylight spectrum.

Lieut. Oliver made the suggestion that inasmuch as it is the public who offend most in the matter of bad lighting, and since it is the electrical contractor-dealer who is more closely in touch with the public, the meetings of illuminating engineers should be attended both by the contractor-dealer and the public. This is undoubtedly a suggestion in the right direction, and we hope something may be done before the present season is over to bring about some joint meetings.

The Ontario Association of Electrical Contractors and Dealers, Toronto District, held an important general meeting in Room G, King Edward Hotel, on Thursday evening, Dec. 12.

The Relation of Light to Health*

By Charles E. De M. Sajous, M.D., Sc. D.

The word "ferment" is steadily being replaced in medical phraseology by the word "enzyme." In the words of Professor Mendel, "Enzymes are no longer thought of exclusively as agents of the digestive apparatus; they enter everywhere into the manifold activities of cells in almost every feature of matabolism." In other words, the same ferments, pepsin, trypsin and others which first prepare foodstuffs in the stomach and intestine, for assimilation by the tissues of the body at large, are the same agents which carry on certain functions in the intimacy of the tissues.

Considerable evidence is available to show that these digestive ferments are carried from the ailmentary canal to the tissue cells by certain white corpuscles of the blood, in which they are readily found. To these white corpuscles belong the phagocytes, which ingest and digest disease germs. We thus have digestive ferments taking part—along with the oxidizing ferment—not only in the vital processes of each tissue cell, but also the defense of the body against disease.

Prevost's theory of mobile temperature equilibrium is now known to apply to radiant heat as well as to heat energy derived from other sources. It is simply that if two bodies of different temperatures are placed close to each other, the warmest of the two will lose by emitting radiant heat which the colder body will take up until the temperature of both is equalized. Briefly, the skin absorbs radiant heat when the cutaneous temperature is lower than that of the radiations received, up to certain limits (influenced by the perspiration and other factors) and the temperature of the tissues of, and beneath, the skin is thus raised.

The penetration of radiant light through the tissues when long wave lengths characterize the rays, is considerable, that of red rays for instance, exceeding one inch. Careful experiments by Rollier showed that solar rays could penetrate the hand and forearm and also, under favorable circumstances, the entire chest.

How does light energy influence the vital process of those tissues and contribue to the defense of the body against disease? Charcot, the French neurologist, as far back as 1859, urged that we should distinguish between the purely chemical effects and those produced by heat. In the present connection we probably are dealing with a process in which the chemico-physical effects credited to oxidizing ferment I have termed "adrenoxidase" and heat both take part, particularly near the surface.

There exists immediately under the superficial tissue a great system of small interwoven canals which, so to say, act as sewers of the tissue cells. They serve not only to carry off, but also to purify the fluids received from those cells by breaking down, as far as possible, the wastes and detritus that they form while carrying on the process which constitutes their life. These channels are interspersed with glands that contain phagocytes, i. e., cells of the type that destroy, by means of their digestive ferments, disease germs and other harmful substances that the small canals carry to them from every direction. This system of lympy channels and glands, known as the lymphatic system, is a prominent weapon of defense. Everyone has seen lymph, a whitish viscid fluid, collect on abrasions, and also enlarged glands on the neck of children. These latter are enlarged lymphatic glands trying to destroy bacteria from some source, the tonsils, adenoids, etc., thus preventing general infection.

The beneficial influence of sunlight is readily accounted for when we take the lymphatic system into consideration in addition to the tissue cells, in view of the effect of light energy as manifested by its radiated heat. Indeed,—and this is the dominating factor in the process—the ferments of both kinds previously referred to those which promote tissue oxidation and those that digest and destroy bacteria and organic poisons become, increasingly active as the heat to which they are exposed is increased, and we obtain as results an increase of both vital activity and defensive aggressiveness.

This increased efficiency of ferments under the influence of increased temperature is the method adopted by Nature, according to my own viewpoint. It explains the process we term "fever," long deemed an enemy, but in reality a defensive function calculated to destrop poisonous substances or germs that have found their way into the body fluids and cells from a focus somewhere either in the superficial or deep tissues. In the course of fever, the germ destroyers, or phagocytes, are not alone at work in the blood stream, but the whole internal lining of the bloodvessels themselves is made up of these germ destroying cells. Again, the lymphatic vessels which act as drains for the tissue cells, we have seen, afford additional aid in the defensive process by means of the multitude of phagocyte-laden glands through which the serum obtained from the blood by the tissue cells must pass before it is returned to the circulation.

Of course, abnormally high fever, i. e., fever above 104 degrees F., for instance, may become dangerous in the sense that the very digestive ferments which have their purpose to defend, become too active and begin to digest not only the red blood corpuscles, a process physicians term "hemolysis," but also certain tissues, a process known as "autolysis." To offset these morbid effects of excessive radiation during hot weather, the skin protects the body by perspiring; the water which moistens the skin, by evaporating, keeps the surface temperature within normal limits. The cool baths physicians employ in the treatment of typhoid fever, have the same end in view; they keep the fever within safe limits.

On the whole, the relation of light to health may be summarized, in view of the few data submitted, by the statement that it is intimately bound up with the perpetuation of life, whether the tissues be normal or diseased. It tends to sustain health by promoting, as radiant energy, the activity of the oxidizing ferment adrenoxidase, which sustains the oxidation of tissue cells, an essential function of their life. It tends to defend the cell, when endangered by certain germs and poisons by enhancing through the heat energy developed, the efficiency of the defensive ferments which submit these harmful agencies to digestive destruction.

* A paper presented before the Philadelphia Section of the Illuminating Engineering Society.

Illumination in Stores and Factories*

By Frederick J. Pearson

An absolutely uniform lighting system in an establishment is inferior to a fairly uniform general lighting system supplanted by special lighting where necessary. Artificial lighting is used only for a small portion of the 24 hours and should be intensified to stimulate production. Efficiency, while important, should not always receive consideration to the exclusion of other factors which may result in greater satisfaction, increased sales in a store, etc. Reproduction of a lighting system merely because it was found to be satisfactory elsewhere, without considering the local conditions, may lead into error. Local conditions must govern design. In a store, a uniform general lighting system for all departments should be used as far as practicable in order to simplify maintenance. As few large units as practicable should be

*From a paper presented before the Chicago Section of the Illuminating Engineering Society.

used in order to reduce the initial and operating costs. The fixtures should be of simple outline and in harmony with the surroundings. Fairly dense diffusing globes with gas filled tungsten lamps are desirable. Show case lighting is rather unsatisfactory because of the poor service from the special lamps used. It is, however, necessary to light show cases locally. Show window lighting still suffers to some extent from exposed lamps.

Light conditions in most factories are poor. Good lighting increases production just as it increases sales in a store. Increases of illumination intensity from 6 to 10 foot-candles have increased the cost of lighting by only 1 per cent. and have been found to promote sales by 6 or 7 per cent. **Increase of lighting cost of 2 per cent. in one installation was reflected in an increased factory production of 10 per cent.** In fact improved lighting is one of the greatest of dividend producers whether in the factory, the store or the office. We are still far below the saturation point in artificial lighting.

In discussion, Prof. E. H. Freeman pointed out that the real measure of illumination effectiveness is the ratio between results secured and cost. In factories it is the relation of production to cost of lighting; in stores it is the relation of sales to cost of lighting.

Mr. J. R. Cravath questioned if local show case lighting is necessary.

Mr. O. L. Johnson referred to the difficulty in getting store and factory managers to appreciate the importance of good lighting which can be obtained only by the use of good equipment, well installed, with due respect to the local conditions. He inquired concerning the practice in department store lighting of adapting the lighting to changes among departments, and asked as to the effect of different lighting intensities on different departments from one to another of which shoppers might go.

Answering questions, Mr. Pearson made the following statements:

Show case lighting, although troublesome, is a necessity, because goods in cases cannot be lighted properly from a general illumination system. Merchandise sells better under light of higher intensity. In factories the choice of enclosing globes or reflectors must depend upon local conditions. Both are used in particular cases with success. It has been observed that intensified lighting results in greater activity, more enthusiasm and better sales service. Under daylighting there are on bright days fewer accidents, fewer discharged people, less dissatisfaction among employees. There is also a larger production in the factory and better workmanship. The difference between bright days and dark, cloudy days is really surprisingly large. In artificial lighting, with 7, or 8, or even 9 foot-candles, where formerly 6 were employed, better results have been obtained. Since increasing the illumination intensities employees and customers have both shown more enthusiasm, interest and activity. In the factory 6 or 7 foot-candles of general illumination is used, supplemented by local lighting. In dye houses and bleacheries, 12 to 15 foot-candles is the intensity adopted.

Can't We Run Our Own Business?

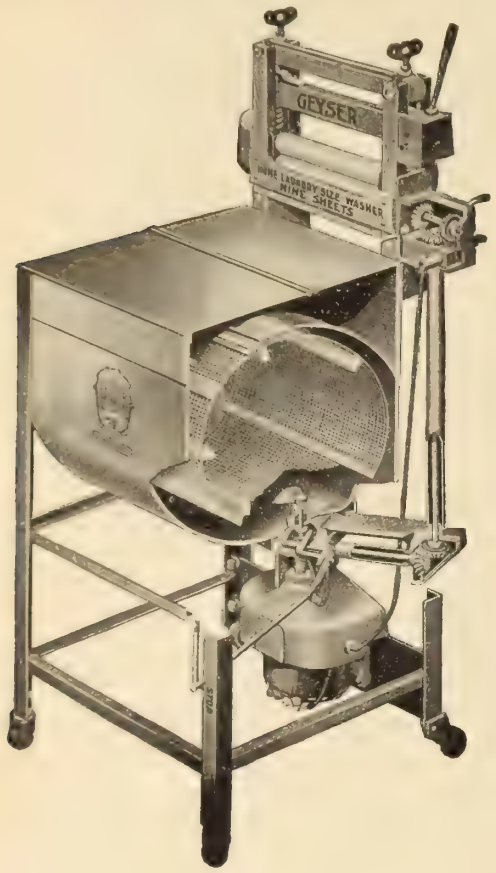
It is pretty generally admitted that there will be an enormous increase in Canada's electrical business. Huge projects that were in preparation when the war cut them short will, it is expected, be gone on with, with the result that in the country districts power will be available. This will mean that THE HARDWARE MEN, WHO HAVE BEEN LEADERS IN DISTRIBUTING ELECTRICAL SPECIALTIES of all kinds, will have a greatly enlarged field of operations.—Extract from a Canadian hardware journal.

Increasing Canada's Exports

The importance of universal expansion in production is admitted on all sides to be, now, more than ever, a national necessity and it is therefore always a pleasure to refer in these columns to instances where Canadian manufacturers not only rise to opportunities offering at the time, but have the forethought to prepare for them beforehand. One of our Montreal manufacturers, the Duncan Electrical Co., Limited, following up their active and successful work in the export field during the last three years, have decided to take one complete exhibition booth at the Lyons Fair, 1919, with a view to taking the fullest advantage of the possibilities offering—we understand that they were the first Canadian factory to apply for space there and we are sure our readers join us in wishing this company the best of results as a reward for their enterprise. A cordial welcome is extended to any Canadians visiting the Duncan Exhibit at the Lyons Fair.

Not Enough Electricity for General Heating

An interesting bulletin (No. 6) has just been issued by the National Advisory Council for Scientific and Industrial Research, entitled "The Heating of Houses—Coal and Electricity Compared." The article is by Mr. A. S. L. Barnes, assistant engineer Hydro-electric Power Commission of Ontario, with the co-operation of the technical staff of the Commission. The bulletin once again points out the futility of any hope that our water powers will ever supply sufficient energy for general heating. On the contrary, the use to which such powers will naturally be put is to operate industrial machinery and thus release large quanties of coal which, in turn, can be used for purely heating purposes. Mr. Barnes calculates that a city the size of Toronto would require a maximum demand of 1,000,000 h.p. As this is approximately twice the amount now being developed at Niagara Falls the hopelessness of general electric heating from our waterpowers is quickly understood.



Electrical Goods Splendid Xmas Sellers

Hardwaremen in Next Two Weeks Have the Best Opportunity They Have Had in Four Years—Buying Public Feels Free to Make Larger Purchases Now War is Over—Don't Forget Attractive Window Display

This is the prominent heading of an article in a Canadian hardware journal. What do you think about it, Mr. Contractor-Dealer? Isn't this YOUR business AND YOUR PROFITS? Are you going to let him get away with it?

Geyser Electric Washers

The illustration herewith is a sectional view of the Geyser Electric Washer, manufactured by the Onward Manufacturing Company, of Kitchener, Ont. The hot suds are forced through the clothes by means of a high speed propeller in the bottom of the tank. The clothes are always under water in a constantly revolving cylinder. Geyser washers are made in seven sizes and are equipped with a swinging wringer, which

can be used in three different positions. All moving parts are enclosed and the tank and frame are electrically welded. The finish is baked enamel—white with gray trimming. The inside of the tank is specially plated, rust-proof and easy to keep clean.

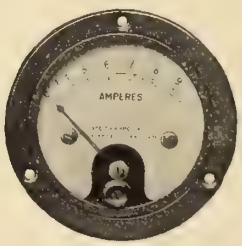
A B.C. Get-Together Supper-Concert

The British Columbia Association of Electrical Contractors and Dealers held a "get-together supper-concert" at the Vancouver Citizens' Club, Vancouver Block, Vancouver, on Thursday, December 12, at 6.45 p.m. Invitations were sent to all electrical men, including manufacturers, central station men, jobbers, salesmen, office staffs, etc. The programme consisted of songs, speeches, choruses. Among the speakers being the following, Geo. Kidd, General Manager B. C. Electric Railway Co.; G. D. Neill, manager, Employers' Association. Subject: "Playing the Game." F. B. Milligan, credit manager, Northern Electric Company. Subject: "Electric Accounting."

Tickets at $1.25 each were distributed by the secretary, Captain W. J. Conway, 406 Yorkshire Building, and a number of representative elecrical men of Vancouver and vicinity.

Hubbell Specialties—The Harvey Hubbell Company of Canada are distributing a folder formally announcing that their Toronto factory is now completely equipped for the manufacture of Hubbell electric specialties, and that they are prepared to make immediate delivery to distributors and retail dealers throughout the Dominion.

The Hotpoint Company Fined for Breaking Rules and Regulations of Hydro Commission



A summons was recently issued against the Hotpoint Co., according to a Kitchener paper, at the instigation of the Inspection Department of the Hydro-Electric Power Commission of Ontario, for having caused to be distributed advertising matter calculated to increased the fire hazard by advocating the use of electric heaters on key sockets, which is contrary to the Rules and Regulations of the Commission.

This is the first case of the kind for which a summons has been issued under the new regulations. Electrical inspection departments all over the continent have had to cope with this same evil and in order to sell heaters the vendors have resorted to a method of wrongly educating the public to the idea that no wiring is necessary.

In spite of warnings of the Inspection Department, the Hotpoint Company failed to comply with the instructions and a fine of $10.00 and costs was imposed by Magistrate Weir.

Meters for Wireless and High Frequency Work

A high grade hot wire measuring instrument designed particularly for wireless and other high frequency work, depending for its operation upon the expansion of a metal strip which is heated by the current to be measured has been developed by the Westinghouse Electric & Manufacturing Co. The slight sag in this conducting strip is magnified several hundred times on the scale by means of wires and a deflecting spring. The conducting strip is made of non-corrosive material. The separating posts have the same temperature coefficient of expansion as the conducting strip, so that the changes in room temperature do not cause an error in the reading of the instrument. The instruments are furnished in two forms, for flush mounting and portable. Similar instruments for switchboard mounting are also sup-

plied. The flush-mounting form, known as type EH, is of the round open-face type. The face is 3 inches in diameter, and the diameter outside the flange is 3¾ inches. It has a black rubberoid case and rim, with white dial. The portable form known as type PH, is mounted on a morocco-leather covered wooden case with heavy glass over the dial. The case is 3¾ inches by 4⅜ inches by 2 inches thick. The scale plate is made of metal, and the scale subtends an arc of 90 degrees, being 2⅜ inches long. The type EH meters have a guaranteed accuracy of 2 per cent. while the type PH, with hand marked scale, can be expected to show an accuracy within 1 per cent. of full scale. Standard meters are for 1, 2, and 5 amperes. Care must be used not to subject the instrument to more than 200 per cent. load.

At a recent meeting of the Ottawa City Council it was agreed to present the street railway purchase question to the electors in the form of three separate by-laws, the first dealing with the purchase of the railway at the expiration of the franchise in 1923, the second with the purchase of the railway at an earlier date by arbitration, and the third with the management of the railway.

Branches: Toronto, Winnipeg, Regina, Calgary Vancouver

Personal

Major T. W. Wilson, of Montreal, formerly on the engineering staff of the Montreal Light, Heat & Power Co., has been decorated with the D.S.O. About a year ago he was awarded the M.C. for conspicuous work at Passchendaele. He has been three years overseas.

Mr. W. D. Neil, Superintendent of the Eastern Division of the C. P. R. telegraphs, has been transferred to the Ontario division, being succeeded by Mr. C. L. Leighty. Mr. W. M. Thompson, Traffic Superintendent of Eastern lines, is promoted to Superintendent of the Eastern Division.

Mr. W. E. Bell, Montreal, has been appointed Acting Division Superintendent of Telegraphs of the Grand Trunk Lines in Alberta and British Columbia. Mr. Bell, whose headquarters are at Edmonton, has jurisdiction over all matters pertaining to the construction and maintenance of telegraph and telephone lines and operation of railroad and commercial telegraphs in the two western provinces. He succeeds Mr. W. J. Rooney, who has been granted leave of absence owing to ill-health.

Obituary

Mr. James T. Mattice, commercial superintendent of the Manitoba Government telephones, died in Winnipeg on November 7. He was for many years on the staff of the Bell Telephone Company in Montreal; in 1906 he removed to Winnipeg, and was the company's contract agent in 1906, when the Manitoba Government took over the telephones.

Mr. Thos. Howe, local manager of the Bell Telephone Company at Tilbury, Ont., died recently.

Mr. G. B. Dowswell, president of Dowswell Lees & Company, Limited, manufacturers of electric washing machines, Hamilton, Ont., died recently.

Current Notes

Fort William, Ont.

The city council of Fort William, Ont., have passed a by-law authorizing an increase in fares on the street railway, subject to approval by the Ontario Railway Board. Under the new arrangement there will be only one rate—straight five cents—for all adults between 5.30 a.m. and midnight, and ten cents straight after midnight. Children's tickets will be eight for a quarter. The new rates will go into effect on New Year's Day.

Montreal, Que.

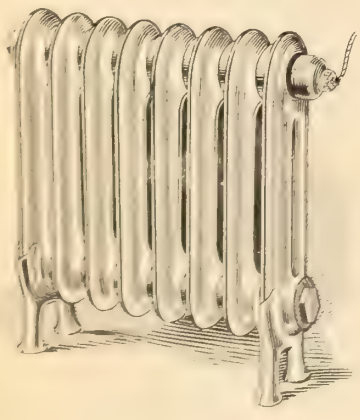
The Montreal office and warehouse of the Canada Wire and Cable Company, Limited, and of the Moloney Electric Co., of Canada, Limited, have been removed to 143 Beaver Hall Hill.

The statement of the Montreal Light, Heat and Power Consolidated for the fiscal half-year ended October shows gains in gross and net revenue and in surplus. The gross stands at $5,297,130, an increase of $474,420 oer the 1917 period; operating charges were $328,642 higher at $2,539,339; net revenue was $145,779 higher at $2,757,791, and surplus better by $145,199 at $2,225,884. During October the gross increase was $64,890; the net $32,391, and the surplus $29,880. The total of the latter item was $444,238, the largest in the history of the company.

Mr. Contractor-Dealer—Is this one of YOUR customers?

Regina, Sask.

The high cost of labor and material is being felt by the Saskatchewan government telephone system and it is announced that rate increases will be necessary in the near future.



Toronto, Ont.

At a recent meeting of the executive of the Hydro-electric Railway Commission a resolution was passed and will be forwarded to the Dominion Government recommending that the Government purchase the Grand Trunk Railway and that the Hydro build electric lines from Toronto to Buffalo, and Toronto to London, the cost of the proposal being in the neighborhood of $25,000,000.

Toronto Street Railway receipts for November were $20,279 less than the same month last year. This, however, is attributed to the loss of revenue on the two days when people were celebrating the signing of the armistice and the street cars were tied up. Every previous month this year has shown an increase in gross receipts and in the city's percentage. Last month's receipts were $547,226, as compared with $537,505 in November, 1917. The city's percentage was $53,010, as compared with $55,823, a decrease of $2,843.

Winnipeg, Man.

Application has been made to the public utilities commission for an increase of from 15 to 20 per cent. in the fares on the lines operated by the Winnipeg, Selkirk and Lake Winnipeg Railway Company. It was stated that the company is at present facing a yearly deficit of $52,000 and that the suggested increase in fares would still leave a deficit of $20,000.

Open Evenings by Appointment

A California dealer, writing in Electrical Merchandising, offers a solution to the difficulty of providing for evening shoppers without the attendant necessity of keeping open every evening. Some months ago, he says, we discovered that a good many people who are busy during the day have not the opportunity to call at our salesrooms during the hours they are ordinarily open, so we looked about for some way to make it possible to reach this class of trade. As it did not appear desirable to keep the showroom open every evening of the week we have adopted the plan of opening the showroom "evenings by appointment." Therefore we had a rubber stamp made and all of the solicitors' cards and certain of the pieces of literature sent out to customers now appear stamped with the following notice:

Sales Department Open Evenings
By Appointment
After 5.30 p.m. Telephone S.R. 725.

In order to make an evening appointment, it is now only necessary for the "prospect" to call one of the salesmen on the telephone, giving the hour and date he wishes to visit the salesroom and he can be assured that a representative of the company will be on hand to answer his questions and demonstrate any device in which he is interested.

How a Vacuum Sweeper Made a Furnace Draw

A vacuum cleaner salesman was recently demonstrating a cleaner and set of attachments at a prospect's home where it was extraordinarily chilly. The lady explained it by telling him that she had been unable to get the proper kind of coal and couldn't get her fire going very good. The salesman quickly suggested that her trouble could be readily solved with the vacuum sweeper and showed exactly how. He put on the blower attachments and held the hose close to the grate and in a few minutes the furnace was approaching red heat She bought the machine and attachments immediately and now uses this method whenever the furnace doesn't draw properly.

Cut Out the Worry

Solderless Connection

Insulating Shell and Cap

Patented Canada 1917.
Patent Pending U. S.

DISCARD THAT BLOW TORCH

Just think! NO BLOW TORCH to carry around with you. No Acid, No Tape, No Solder, No Dirty Hands, No Dirty Canopies, Ceiling, Walls or Carpets, and the job done in one-fifth of the time. **A better job, too.** NO WORRY about the Inspectors. When the Inspector sees the Walger Connectors in place of the old solder and tape method, **he knows** the job is right because it is fool proof. A child could do it.

Passed by UNDERWRITERS' LABORATORIES, CHICAGO

Approved and recommended by HYDRO ELECTRIC COMMISSION OF ONTARIO, TORONTO

Ask your jobber for them or write. Will save time and money.

"Pittsburgh" Reflectors

Increase Light 500%

BY TEST

Illustration shows "Pittsburgh" Reflector No. 50 for 100 or 150 Watt Lamp. Dimensions: Height, 9½ inches, Width 10 inches. Holder 2¼ in. Form "O".

They are scientifically formed to obtain the maximum of light on the window trim. "Pittsburgh" Reflectors have attained extensive sales for window lighting, because of their saving of current and their dependability to increase lighting efficiency.

TRADE DAUM MARK **Renewable Fuses**

FOR ELECTRIC LIGHT AND POWER

Always were the simplest fuses in construction on the market. The new Type "B," Form 4, has been reduced to the fewest parts—four metal parts of solid brass, a fibre shell and the fuse strip. Caps are removed by a twist of the wrist and as easily tightened, holding the fuse strip in intimate metal-to-metal contact.

Friends of the Electrician

"ANTI-SULPHURIC" ENAMEL
The only reliable protection against the action of acid and chemical fumes.

"FERRODOR"
Rustproof elastic paint. Superior to Graphite or Red Lead. Defies all climatic conditions.

"DRIOROL"
Oil-proof Enamel. Dries quickly over greasy and oily surfaces. Not affected by lubricating or transformer oils.

"ARMOUR"
Fire-resisting paint, or colorless solution.

"ARMACELL"
Possesses the highest insulating qualities of any varnish on the market.

"OHMALINE"
Black, quick air-drying insulating composition. Also supplied for stoving, and as a solid insulating compound.

"SHAYDOLITE"
for coloring electric lamps. Used in the Royal Navy. Weatherproof. Dries rapidly.

"ARMABRON"
Bitumen protective paint, elastic, acid-resisting, weatherproof.

DOSSERT CONNECTORS

The Superintendent of one of the largest electrical contracting firms writes us:
"The workmen have formed the habit of using Dossert Connectors for all kinds of connections and consider it a hardship if they are called upon to perform the tedious and laborious task of making a soldered joint with its attendant acid fumes, gasoline torch smoke and burned fingers."

Ask the man who makes the joint!

SQUARE D

SWITCHES

D

THE ORIGINAL SAFETY SWITCH

—and Your Verdict?

If there is one open knife switch in your plant a fatal accident like this is *possible.*

If you study the statistics regarding accidents due to contact with exposed switches you will realize how *probable* it is.

Both consideration for your employees and business judgment dictates that you replace every exposed knife switch with a safe Square D.

The Square D Steel Enclosed Switch is *more* than a personal safety device. Its lock-off device, quick, positive action, steel enclosure and external operation are features which protect *both* men and equipment.

Your electrician will tell you how and why.

ECONOMY
RENEWABLE
FUSES

protect millions of circuits and billions of dollars worth of property in thousands of plants representing every branch of industry.

They are used by the U. S. Navy, leading powder and munitions plants, ship yards, steel mills and others who put accuracy and safety before anything else. They cut annual fuse maintenance costs 80 per cent., because an inexpensive little "Drop Out" Renewal Link restores a blown Economy Fuse to its original efficiency.

No special tools or experience needed to replace the link and renew the fuse. Anyone can do it in a jiffy.

Order from your Jobber. Ask for Catalog 20.

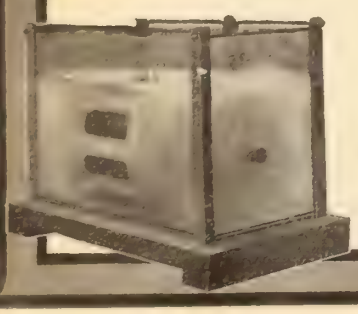
NOTICE

To Manufacturers and Others

We are not only builders of the famous Lincoln Arc Welder, but we are also in a position to quote you on welding and repairs to your machinery or boilers. We have complete equipment for this work and can have our plant brought to the job on short notice.

We keep a staff of operators ready for any emergency.

Let us quote you on your welding and save many dollars on machines that you would otherwise scrap. A phone call will bring a man in a hurry.



You can save 50 per cent.—very often more—by doing your boiler plate work with a Lincoln Arc Welder instead of rivetting it.

Lincoln-welded joints are 100 per cent. strong—rivetted joints are no stronger than the rivets themselves.

It has been adopted by boiler shops, structural steel works, street car and railroad companies as being the most practical solution of the present labor shortage.

ESTABLISHED 1849
BRADSTREET'S
Offices Throughout the Civilized World.
Executive Office:
Nos. 346 and 348 Broadway, New York City, U. S. A.
THE BRADSTREET COMPANY gathers information that reflects the financial condition and the controlling circumstances of every seeker of mercantile credit. Its business may be defined as of the merchants, by the merchants, for the merchants. In procuring, verifying and promulgating information no effort is spared, and no reasonable expense considered too great, that the results may justify its claim as an authority on all matters affecting commercial affairs and mercantile credit. Its offices and connections have been steadily extended, and it furnishes information concerning mercantile persons throughout the civilized world.
Subscriptions are based on the service furnished and are available only by reputable wholesale jobbing and manufacturing concerns, and by responsible and worthy financial, fiduciary and business corporations. Specific terms may be obtained by addressing the company at any of its offices. Correspondence invited.
THE BRADSTREET COMPANY
Offices in Canada: Halifax, N.S.; Hamilton, Ont.; London, Ont.; Montreal, Que.; Ottawa, Ont.; Quebec, Que.; St. John, N.B.; Toronto, Ont.; Vancouver, B.C.; Victoria, B.C.; Winnipeg, Man.; Calgary, Alta.; Edmonton, Alta.

A Lost Opportunity

As a wiring contractor, how many times have you turned down orders to repair the Motors or dynamos of your customers and let them send their work to the maker?

How much have YOU lost in prestige through not being able to take care of your customers' business?

How much have YOU lost in Profit on this business?

Get the habit of handling these repairs. Send them to a **Specialist in Repairs.** Don't send them to the maker. Your customer can do that, and he's already sick of it. The service is too slow. He wants quick work and an absolutely reliable job. You can give it to him.

Make up your mind now. Say "I'm going to get something out of the next repair job in this town."

You have the work of taking out and re-installing the machine **(Profit).** Send us the machine or part with a description of its action or symptom. We'll rush it through for you, give you an A1 job and you come in again on the **Trade Discount (More Profit).**

Others are doing it. Why not you? Write about it.
